## Report:

The goal of the project was to study the magnetic and electronic phase transitions in the $\mathrm{GdFe}_{3}\left(\mathrm{BO}_{3}\right)_{4}$ syngle crystals induced by high-pressures and cryogenic temperatures by the Synchrotron Mössbauer Spectrometry (SMS) on the Fe-57 nucleis.

We have successfully collected sets of SMS spectra of the $\mathrm{GdFe}_{3}\left(\mathrm{BO}_{3}\right)_{4} \mathrm{Fe}-57$ isotope enriched single crystal in the Diamon Anvil Cell (DAC) under pressure till to 73 GPa in the temperature range $2.5-295 \mathrm{~K}$. All the data were obtained in the ESRF membrane DAC.

Figure 1. (a) - original $G d^{57} \mathrm{Fe}_{3}\left(\mathrm{BO}_{3}\right)_{4}$ single crystal; (b) - small part of original $G d^{57} \mathrm{Fe}_{3}\left(\mathrm{BO}_{3}\right)_{4}$ single crystal in the DAC at $P=0.3 \mathrm{GPa}$; $(c)-(h)$ - synchrotron Mössabuer spectra of the $G d^{57} \mathrm{Fe}_{3}\left(B O_{3}\right)_{4}$ single crystal in the DAC at some pressures and temperatures.

A preliminary analysis of the experimental data obtained confirmed the existence of two phase transitions at pressures of about 30 GPa and 50 GPa , with a change in the state of iron $\mathrm{Fe}^{3+}$ ions from highspin to low-spin and complete suppression of magnetic ordering at pressures above 50 GPa . A complete data analysis is in progress. The quality and volume of the collected data seems to be sufficient to reach the scientific goals of proposal but only for the $\mathrm{GdFe}_{3}\left(\mathrm{BO}_{3}\right)_{4} \mathrm{Fe}-57$ enriched compound. It seems necessary to continue the high pressure SMS measurements for $\mathrm{NdFe}_{3}\left(\mathrm{BO}_{3}\right)_{4}$ and $\mathrm{HoFe}_{3}\left(\mathrm{BO}_{3}\right)_{4}$ single crystals $\mathrm{Fe}-57$ isotope enriched.
