The TANGO control system manual

Version 5.3

photos by Ricardo Steinmann

The TANGO team

28th July 2005
# Contents

1 Introduction ................................................................. 19
   1.1 Introduction to device server ...................................... 19
   1.2 Device server history ............................................... 20

2 Getting Started ............................................................. 21
   2.1 A Java TANGO client .................................................. 21
   2.2 A C++ TANGO client ................................................... 23
   2.3 A TANGO device server ............................................... 25
      2.3.1 The commands and attributes code in C++ .................. 25
         2.3.1.1 The DevSimple command .................................. 25
         2.3.1.2 The DevArray command .................................... 26
         2.3.1.3 The DevString command .................................... 26
         2.3.1.4 The DevStrArray command ................................. 27
         2.3.1.5 The DevStruct command .................................... 28
         2.3.1.6 The three attributes ....................................... 28
      2.3.2 The commands and attributes code in java .................. 30
         2.3.2.1 The DevSimple command .................................. 30
         2.3.2.2 The DevArray command .................................... 31
         2.3.2.3 The DevString command .................................... 31
         2.3.2.4 The DevStrArray command ................................. 32
         2.3.2.5 The DevStruct command .................................... 32
         2.3.2.6 The three attributes ....................................... 33

3 The TANGO device server model ........................................... 37
   3.1 Introduction to CORBA .............................................. 37
   3.2 The model ............................................................ 38
   3.3 The device ........................................................... 38
      3.3.1 The commands .................................................. 38
      3.3.2 The TANGO attributes ......................................... 39
      3.3.3 Command or attributes? ....................................... 39
      3.3.4 The CORBA attributes ......................................... 39
      3.3.5 The remaining CORBA operations ............................. 40
      3.3.6 The special case of the device state and status ......... 40
      3.3.7 The device polling ............................................. 41
   3.4 The server ............................................................ 41
   3.5 The Tango Logging Service ......................................... 41
   3.6 The database .......................................................... 42
   3.7 The Application Programmers Interfaces .......................... 42
      3.7.1 Rules of the API ............................................... 42
      3.7.2 Communication between client and server using the API ... 43
      3.7.3 Tango events ................................................... 43
4 Writing a TANGO client using TANGO APIs 46
  4.1 Introduction .................................. 46
  4.2 Getting Started ................................ 46
  4.3 Basic Philosophy .............................. 46
  4.4 Request model ................................ 46
    4.4.1 Synchronous model ....................... 47
    4.4.2 Asynchronous model ....................... 48
  4.5 Events ........................................ 48
    4.5.1 Introduction ............................... 48
    4.5.2 Event definition ........................... 49
    4.5.3 Event types ............................... 49
    4.5.4 Event filtering ............................ 50
    4.5.5 Application Programmer’s Interface .... 51
      4.5.5.1 Configuring events .................. 51
      4.5.5.2 C++ Clients ........................... 52
      4.5.5.3 Java Clients ........................... 54
  4.6 Group .......................................... 55
    4.6.1 Getting started with Tango group ....... 56
    4.6.2 Forward or not forward? ................ 58
    4.6.3 Executing a command ..................... 58
      4.6.3.1 Obtaining command results .......... 59
      4.6.3.2 Case 1: a command, no argument ..... 60
      4.6.3.3 A few words on error handling and data extraction ..... 60
      4.6.3.4 Case 2: a command, one argument ... 65
      4.6.3.5 Case 3: a command, several arguments ... 66
    4.6.4 Reading an attribute ..................... 70
      4.6.4.1 Obtaining attribute values .......... 70
      4.6.4.2 A few words on error handling and data extraction ..... 70
    4.6.5 Writing an attribute ...................... 73
      4.6.5.1 Obtaining acknowledgement .......... 73
      4.6.5.2 Case 1: one value for all devices ... 74
      4.6.5.3 Case 2: a specific value per device ... 76
  4.7 Reconnection and exception .................. 79
  4.8 Compiling and linking a Tango client ....... 79

5 TANGO Java API ................................ 81
  5.1 Introduction ................................ 82
    5.1.1 Description ................................ 82
    5.1.2 Basic Philosophy .......................... 82
    5.1.3 Classes .................................... 83
      5.1.3.1 Data object classes .................. 83
      5.1.3.2 Asynchronous callback related classes .. 83
      5.1.3.3 Devices and Database access classes .... 83
    5.1.4 Reporting errors ............................ 83
    5.1.5 Compiling a Java client .................. 84
      5.1.5.1 Supported java release ................ 84
      5.1.5.2 Setting CLASSPATH and other environment variables ........ 84
  5.2 Data object classes .......................... 84
    5.2.1 DeviceData class .......................... 84
      5.2.1.1 Public methods ........................ 84
      5.2.1.2 Example ................................ 85
    5.2.2 DeviceDataHistory .......................... 85
      5.2.2.1 Public fields .......................... 85
      5.2.2.2 Public methods ........................ 86
### CONTENTS

5.2.3 CommandInfo ................................................. 86
   5.2.3.1 Public fields ........................................ 86
5.2.4 AttributeInfo .................................................. 87
   5.2.4.1 Public fields ........................................ 87
5.2.5 AttributeInfoEx ................................................ 87
   5.2.5.1 Public fields ........................................ 87
5.2.6 AttributeAlarmInfo .............................................. 88
   5.2.6.1 Public fields ........................................ 88
5.2.7 AttributeEventInfo ............................................ 88
   5.2.7.1 Public fields ........................................ 88
5.2.8 ChangeEventInfo ................................................ 88
   5.2.8.1 Public fields ........................................ 88
5.2.9 PeriodicEventInfo ............................................. 88
   5.2.9.1 Public fields ........................................ 89
   5.2.9.2 Public fields ........................................ 89
5.2.10 DbDatum .......................................................... 89
   5.2.10.1 Public fields ........................................ 89
   5.2.10.2 public methods ...................................... 89
   5.2.10.3 Example .............................................. 90
5.2.11 DbAttribute ...................................................... 90
   5.2.11.1 Public fields ........................................ 90
   5.2.11.2 Public methods ...................................... 90
   5.2.11.3 Example .............................................. 92
5.2.12 DeviceAttribute ................................................. 92
   5.2.12.1 Public methods ...................................... 92
5.2.13 DbDevInfo Class .................................................. 94
   5.2.13.1 Public fields ........................................ 94
   5.2.13.2 Public methods ...................................... 94
   5.2.13.3 Example .............................................. 94
5.2.14 DbDevImportInfo class ........................................ 94
   5.2.14.1 Public fields ........................................ 94
   5.2.14.2 Public methods ...................................... 94
   5.2.14.3 Example .............................................. 95
5.2.15 DbDevExportInfo class ........................................ 95
   5.2.15.1 Public fields ........................................ 95
   5.2.15.2 Public methods ...................................... 95
   5.2.15.3 Example .............................................. 95
5.3 Asynchronous callback related classes .............................. 95
   5.3.1 CallBack class ............................................. 95
   5.3.1.1 Public methods ....................................... 96
5.3.2 CmdDoneEvent class ............................................ 96
   5.3.2.1 Public fields ........................................ 96
5.3.3 AttrReadEvent class ............................................ 96
   5.3.3.1 Public fields ........................................ 96
5.3.4 AttrWrittenEvent class ........................................ 97
   5.3.4.1 Public fields ........................................ 97
5.3.5 EventData class .................................................. 97
   5.3.5.1 Public fields ........................................ 97
5.4 Devices access .................................................. 97
   5.4.1 DeviceProxy class .......................................... 97
   5.4.1.1 Tango database management for Tango device ........... 97
   5.4.1.2 The exported device management methods ............... 100
   5.4.1.3 Attribute methods ................................... 102
   5.4.1.4 Polling methods. ...................................... 105
5.4.1.5 Asynchronous command oriented methods .................................. 106
5.4.1.6 Asynchronous attribute related methods ................................. 109
5.4.1.7 Miscellaneous asynchronous related methods ....................... 112
5.4.1.8 Event related methods ..................................................... 114
5.4.1.9 Logging related methods ............................................... 114
5.4.1.10 TACO Device access .................................................. 115
5.4.2 AttributeProxy class ......................................................... 118
   5.4.2.1 Attribute access related methods ................................ 119
   5.4.2.2 Asynchronous call related methods .................................. 121
   5.4.2.3 Events related methods ............................................. 122
5.5 Utility classes ................................................................. 122
   5.5.1 ApiUtil class ............................................................... 122
5.6 Multiple devices access ..................................................... 124
   5.6.1 The Group class .......................................................... 124
      5.6.1.1 Constructor .......................................................... 124
      5.6.1.2 Group Management Related Methods ............................ 124
      5.6.1.3 "A la" DeviceProxy Methods .................................... 127
5.7 Event related classes ........................................................ 131
   5.7.1 TangoEventsAdapter class .............................................. 131
   5.7.2 ITangoPeriodicListener interface ..................................... 133
   5.7.3 ITangoChangeListener interface ....................................... 133
   5.7.4 ITangoQualityChangeListener interface .............................. 134
   5.7.5 ITangoArchiveListener interface ..................................... 134
   5.7.6 TangoPeriodicEvent class ............................................ 134
   5.7.7 TangoChangeEvent class ................................................ 134
   5.7.8 TangoQualityChangeEvent class ..................................... 134
   5.7.9 TangoArchiveEvent class ............................................. 135
5.8 Database access classes ................................................... 135
   5.8.1 Database class ........................................................... 135
      5.8.1.1 General information methods .................................. 135
      5.8.1.2 Object property methods ....................................... 137
      5.8.1.3 Device Methods ................................................... 139
      5.8.1.4 Device property methods ....................................... 141
      5.8.1.5 Device attribute methods ...................................... 143
      5.8.1.6 Server methods ................................................... 145
      5.8.1.7 Class property methods ........................................ 146
      5.8.1.8 Class attribute Methods .................................... 147
   5.8.2 DbClass class ............................................................... 149
      5.8.2.1 Class property methods ....................................... 149
      5.8.2.2 Class attribute methods ...................................... 150
      5.8.2.3 General information methods ................................ 151
      5.8.2.4 Device aliases related methods ............................... 152
      5.8.2.5 Device aliases related methods ............................... 152
   5.8.3 DbServer class ............................................................. 153

6 The TANGO C++ Application Programmer Interface ........................................ 155
   6.1 Tango::DeviceProxy() ...................................................... 155
      6.1.1 Constructors .......................................................... 155
         6.1.1.1 DeviceProxy::DeviceProxy(string &name, CORBA::ORB *orb—NULL) 155
         6.1.1.2 DeviceProxy::DeviceProxy(const char *name, CORBA::ORB *orb—NULL) 155
      6.1.2 Miscellaneous methods ............................................. 155
         6.1.2.1 DeviceInfo DeviceProxy::info() ............................... 155
         6.1.2.2 DeviceState DeviceProxy::state() ................................ 156
6.1.2.3 string DeviceProxy::status() .................................................. 156
6.1.2.4 int DeviceProxy::ping() ...................................................... 156
6.1.2.5 void DeviceProxy::set_timeout_millis(int timeout) ................. 156
6.1.2.6 int DeviceProxy::get_timeout_millis() ................................ 157
6.1.2.7 int DeviceProxy::get_idl_version() .................................... 157
6.1.2.8 void DeviceProxy::set_source(DeviceSource source) .............. 157
6.1.2.9 DeviceSource DeviceProxy::get_source() ............................. 157
6.1.2.10 vector<string> *DeviceProxy::black_box(int n) .................... 157
6.1.2.11 string DeviceProxy::name() ............................................... 157
6.1.2.12 string DeviceProxy::adm_name() ....................................... 157
6.1.2.13 string DeviceProxy::dev_name() ....................................... 157
6.1.2.14 string DeviceProxy::description() .................................... 157
6.1.2.15 DbDevImportInfo DeviceProxy::import_info() ....................... 158
6.1.2.16 void DeviceProxy::set_transparency_reconnection(bool flag) .... 158
6.1.2.17 bool DeviceProxy::get_transparency_reconnection() ................ 158
6.1.2.18 string DeviceProxy::alias() ............................................. 158
6.1.3 Synchronous command oriented methods .................................. 158
6.1.3.1 CommandInfo DeviceProxy::command_query(string command) .... 158
6.1.3.2 CommandInfoList *DeviceProxy::command_list_query() ............ 158
6.1.3.3 DeviceData DeviceProxy::command_inout(string) .................... 159
6.1.3.4 DeviceData DeviceProxy::command_inout(const char *) ............ 159
6.1.3.5 DeviceData DeviceProxy::command_inout(string, DeviceData &) ... 159
6.1.3.6 DeviceData DeviceProxy::command_inout(const char *, Device- 

6.1.4 Synchronous attribute related methods ................................ 160
6.1.4.1 Compatibility between Tango release 4 and release 5 regarding 

6.1.4.2 AttributeInfoEx DeviceProxy::attribute_query(string attribute) 160
6.1.4.3 AttributeInfoList *DeviceProxy::attribute_list_query() ........... 160
6.1.4.4 AttributeInfoListEx *DeviceProxy::attribute_list_query_ex() .... 160
6.1.4.5 vector<string> *DeviceProxy::get_attribute_list() ................ 160
6.1.4.6 AttributeInfoList *DeviceProxy::get_attribute_config(vector<string>&) 161
6.1.4.7 AttributeInfoListEx *DeviceProxy::get_attribute_config_ex(vector<string>&) 161
6.1.4.8 AttributeInfoEx DeviceProxy::get_attribute_config(string&) .... 162
6.1.4.9 void DeviceProxy::set_attribute_config(AttributeInfoList &) .... 162
6.1.4.10 void DeviceProxy::set_attribute_config(AttributeInfoListEx &) 162
6.1.4.11 vector<DeviceAttribute> *DeviceProxy::read_attributes(vector<string>&) 163
6.1.4.12 DeviceAttributeDeviceProxy::read_attribute(string&) ........... 163
6.1.4.13 DeviceAttributeDeviceProxy::read_attribute(const char *) ....... 163
6.1.4.14 void DeviceProxy::write_attributes(vector<DeviceAttribute>&) . 163
6.1.4.15 void DeviceProxy::write_attribute(DeviceAttribute&) ........... 164
6.1.4.16 vector<DeviceAttributeHistory> *DeviceProxy::attribute_history(string 

6.1.4.17 vector<DeviceAttributeHistory> *DeviceProxy::attribute_history(const 

6.1.5 Asynchronous command oriented methods ............................. 165
6.1.5.1 long DeviceProxy::command_inout_async(string &name, bool forget) 165
6.1.5.2 long DeviceProxy::command_inout_async(const char *name, bool forget) 165
6.1.5.3 long DeviceProxy::command_inout_async(string &name, Device- 

6.1.6 Asynchronous attribute related methods ................................ 165
6.1.5.4 long DeviceProxy::command_inout_asynch(const char *name, DeviceData &argin, bool forget) ........................................... 165
6.1.5.5 DeviceData DeviceProxy::command_inout_reply(long id) .... 165
6.1.5.6 DeviceData DeviceProxy::command_inout_reply(long id, long timeout) ................................................................. 166
6.1.5.7 void DeviceProxy::command_inout_asynch(string &name, CallBack &cb) ................................................................. 166
6.1.5.8 void DeviceProxy::command_inout_asynch(const char *name, CallBack &cb) ................................................................. 166
6.1.5.9 void DeviceProxy::command_inout_asynch(string &name, DeviceData &argin, CallBack &cb) ........................................... 166
6.1.5.10 void DeviceProxy::command_inout_asynch(const char *name, DeviceData &argin, CallBack &cb) ........................................... 167

6.1.6 Asynchronous attribute related methods ................................. 167
6.1.6.1 long DeviceProxy::read_attribute_asynch(string &name) .......... 167
6.1.6.2 long DeviceProxy::read_attribute_asynch(const char *name) .......... 167
6.1.6.3 long DeviceProxy::read_attributes_asynch(vector<string> &names) ............. 167
6.1.6.4 DeviceAttribute *DeviceProxy::read_attribute_reply(long id) ............. 167
6.1.6.5 DeviceAttribute *DeviceProxy::read_attribute_reply(long id, long timeout) ............. 167
6.1.6.6 vector_DeviceAttribute> *DeviceProxy::read_attributes_reply(long id) ............. 168
6.1.6.7 vector_DeviceAttribute> *DeviceProxy::read_attributes_reply(long id, long timeout) ............. 168
6.1.6.8 long DeviceProxy::write_attribute_asynch(DeviceAttribute &argin) ............. 168
6.1.6.9 long DeviceProxy::write_attributes_asynch(vector_DeviceAttribute> &argin) ............. 168
6.1.6.10 void DeviceProxy::write_attribute_reply(long id) ............. 168
6.1.6.11 void DeviceProxy::write_attribute_reply(long id, long timeout) ............. 169
6.1.6.12 void DeviceProxy::write_attributes_reply(long id) ............. 169
6.1.6.13 void DeviceProxy::write_attributes_reply(long id, long timeout) ............. 169
6.1.6.14 void DeviceProxy::write_attribute_asynch(string &name, CallBack &cb) ............. 169
6.1.6.15 void DeviceProxy::write_attribute_asynch(const char *name, CallBack &cb) ............. 169
6.1.6.16 void DeviceProxy::write_attributes_asynch(vector<string> &names, CallBack &cb) ............. 169
6.1.6.17 void DeviceProxy::write_attribute_asynch(DeviceAttribute &argin, CallBack &cb) ............. 170
6.1.6.18 void DeviceProxy::write_attribute_asynch(DeviceAttribute &argin, CallBack &cb) ............. 170

6.1.7 Miscellaneous asynchronous related methods ......................... 170
6.1.7.1 long DeviceProxy::pending_asynch_call(async_req_type req) ............. 170
6.1.7.2 void DeviceProxy::get_asynch_replies() ................................ 170
6.1.7.3 void DeviceProxy::get_asynch_reply(long timeout) .................. 171

6.1.8 Polling related methods .................................................. 171
6.1.8.1 bool DeviceProxy::is_command_pured(string &cmd_name) .............. 171
6.1.8.2 bool DeviceProxy::is_command_pured(const char *cmd_name) .............. 171
6.1.8.3 bool DeviceProxy::is_attribute_pured(string &attr_name) .............. 171
6.1.8.4 bool DeviceProxy::is_attribute_pured(const char *attr_name) .............. 171
6.1.8.5 int DeviceProxy::get_command_poll_period(string &cmd_name) .............. 171
6.1.8.6 int DeviceProxy::get_command_poll_period(const char *cmd_name) .............. 172
6.1.8.7 int DeviceProxy::get_attribute_poll_period(string &attr_name) .............. 172
6.1.8.8 int DeviceProxy::get_attribute_poll_period(const char *attr_name) .............. 172
6.6.7.4  void AttributeProxy::put_property(DbData& ) ........................................... 197
6.6.7.5  void AttributeProxy::delete_property (string&, DbData& ) .................................. 197
6.6.7.6  void AttributeProxy::delete_property (vector<string>& , DbData& ) .................... 197
6.6.7.7  void AttributeProxy::delete_property (DbData& ) ........................................... 198

6.7  Tango::ApiUtil ................................................................. 198
6.7.1  static ApiUtil *ApiUtil::instance() ..................................................... 198
6.7.2  static void ApiUtil::cleanup() ......................................................... 198
6.7.3  long ApiUtil::pending_asynch_call (async_req_type req) ............................. 198
6.7.4  void ApiUtil::get_asynch_replies() ................................................... 198
6.7.5  void ApiUtil::get_asynch_replies (long timeout) ...................................... 198
6.7.6  void ApiUtil::set_asynch_cb_sub_model (cb_sub_model) ................................ 199
6.7.7  cb_sub_model ApiUtil::get_asynch_cb_sub_model() ...................................... 199

6.8  Asynchronous callback related classes .................................................. 199
6.8.1  Tango::Callback ............................................................... 199
6.8.1.1  void CallBack::cmd_ended (CmdDoneEvent *event) .................................. 199
6.8.1.2  void CallBack::attr_read (AttrReadEvent *event) ................................. 199
6.8.1.3  void CallBack::attr_written (AttrWrittenEvent *event) .......................... 199
6.8.1.4  void CallBack::push_event (EventData *event) ....................................... 199
6.8.2  Tango::CmdDoneEvent .......................................................... 199
6.8.3  Tango::AttrReadEvent ........................................................................ 200
6.8.4  Tango::AttrWrittenEvent ..................................................................... 200
6.8.5  Tango::EventData ............................................................................. 200

6.9  Tango::Group .......................................................... 201
6.9.1  Constructor and Destructor .............................................................. 201
6.9.1.1  Group::Group (const std::string& name) ............................................ 201
6.9.1.2  Group::Group () ........................................................................... 201
6.9.2  Group Management Related Methods .................................................. 201
6.9.2.1  void Group::add (Group* group) ........................................................ 201
6.9.2.2  void Group::add (const std::string& pattern) ....................................... 201
6.9.2.3  void Group::add (const std::vector<string>& & patterns) ...................... 201
6.9.2.4  void Group::remove (const std::string& pattem, bool fwd = true) .......... 201
6.9.2.5  void Group::remove (const std::vector<std::string>& & patterns, bool 
               fwd = true) .............................................................................. 202
6.9.2.6  void Group::remove_all (void) .......................................................... 202
6.9.2.7  bool Group::contains (const std::string& pattern, bool fwd = true) ........ 202
6.9.2.8  DeviceProxy* Group::get_device (const std::string& device_name) ............. 203
6.9.2.9  DeviceProxy* Group::get_device (long idx) ........................................... 203
6.9.2.10 DeviceProxy* Group::operator[] (long i) ............................................. 203
6.9.2.11 Group* Group::get_group (const std::string& name) .............................. 204

Chapter 1

Introduction

1.1 Introduction to device server

Device servers were first developed at the European Synchrotron radiation Facility (ESRF) for controlling the 6 Gev synchrotron radiation source. This document is a Programmer’s Manual on how to write TANGO device servers. It will not go into the details of the ESRF, nor its Control System nor any of the specific device servers in the Control System. The role of this document is to help programmers faced with the task of writing TANGO device servers.

Device servers have been developed at the ESRF in order to solve the main task of Control Systems viz provide read and write access to all devices in a distributed system. The problem of distributed device access is only part of the problem however. The other part of the problem is providing a programming framework for a large number of devices programmed by a large number of programmers each having different levels of experience and style.

Device servers have been written at the ESRF for a large variety of different devices. Devices vary from serial line devices to devices interfaced by field-bus to memory mapped VME cards or PC cards to entire data acquisition systems. The definition of a device depends very much on the user’s requirements. In the simple case a device server can be used to hide the serial line protocol required to communicate with a device. For more complicated devices the device server can be used to hide the entire complexity of the device timing, configuration and acquisition cycle behind a set of high level commands.

In this manual the process of how to write TANGO client (applications) and device servers will be treated. The manual has been organized as follows:

- A getting started chapter.
- The TANGO device server model is treated in chapter 3
- Generalities on the Tango Application Programmer Interfaces are given in chapter 4
- The TANGO Java client Application Programmer Interface is described in chapter 5
- Chapter 6 describes the TANGO C++ client Application Programmer Interface
- Chapter 7 is an a programmer’s guide for the Tango Application ToolKit (TangoATK). This is a Java toolkit to help Tango Java application developers.
- How to write a TANGO device server is explained in chapter 8
- Chapter 9 describes advanced Tango features

Throughout this manual examples of source code will be given in order to illustrate what is meant. Most examples have been taken from the StepperMotor class - a simulation of a stepper motor which illustrates how a typical device server for a stepper motor at the ESRF functions.
1.2 Device server history

The concept of using device servers to access devices was first proposed at the ESRF in 1989. It has been successfully used as the heart of the ESRF Control System for the institute accelerator complex. This Control System has been named TACO\(^1\). Then, it has been decided to also use TACO to control devices in the beam-lines. Today, more than 30 instances of TACO are running at the ESRF. The main technologies used within TACO are the leading technologies of the 80's. The Sun Remote Procedure Call (RPC) is used to communicate over the network between device server and applications, OS-9 is used on the front-end computers, C is the reference language to write device servers and clients and the device server framework follows the MIT Widget model. In 1999, a renewal of the control system was started. In June 2002, Soleil and ESRF officially decide to collaborate to develop this renewal of the old TACO control system. Soleil is a French synchrotron radiation facility currently under construction in the Paris suburbs. See [4] and [5] to get all information about Soleil. In December 2003, Elettra joins the club. Elettra is an Italian synchrotron radiation facility located in Trieste. See [20] to get all information about Elettra. The new version of the Elettra/ESRF/Soleil control system is named TANGO\(^2\) and is based on the 21 century technologies:

- CORBA\(^3\) to communicate between device server and clients
- C++ and Java as reference programming languages
- Linux, Solaris and Windows-NT as operating systems
- Modern object oriented design pattern

---

\(^1\)TACO stands for Telescope and Accelerator Controlled with Objects
\(^2\)TANGO stands for TACo Next Generation Object
\(^3\)CORBA stands for Common Object Request Broker Architecture
Chapter 2

Getting Started

2.1 A Java TANGO client

The quickest way of getting started is by studying this example:

```java
/**
 * Example of a client using the TANGO Api
 */
import fr.esrf.Tango.*;
import fr.esrf.TangoDs.*;
import fr.esrf.TangoApi.*;

class TestDatabase
{
    public static void main (String args[])
    {
        try
        {
            // Database Management.
            //---------------------------

            // Create a Database object or retrieve an existing connection
            Database dbase = ApiUtil.get_db_obj();

            // Get and display database info.
            System.out.println(dbase.get_info());

            // Build a DbDevInfo object (name, class, server)
            // to add a device into the database.
            String devname = "tango/admin/corvus";
            DbDevInfo devinfo = new DbDevInfo(devname, "Starter", "Starter/corvus");
            dbase.add_device(devinfo);

            // Get and display info about device import.
            DbDevImportInfo imp_info = dbase.import_device(devname);
            System.out.println(imp_info);

            // Update device properties.
```
devname = "my/serial/device";
DbDatum[] prop;
prop = new DbDatum[3];
prop[0] = new DbDatum("baudrate", 19200);
prop[1] = new DbDatum("parity", "none");
prop[2] = new DbDatum("stopbits", 1);
dbase.put_device_property(devname, prop);

// Query the database for device properties.
int baud = 9600;
String parity = "none";
short stop = 1;
String[] propnames = {"baudrate", "parity", "stopbits"};
prop = dbase.get_device_property(devname, propnames);
if (!prop[0].is_empty()) baud = prop[0].extractLong();
if (!prop[1].is_empty()) parity = prop[1].extractString();
if (!prop[2].is_empty()) stop = prop[2].extractShort();

// Device Management

// get device properties as from database.
DeviceProxy dev = new DeviceProxy("my/serial/device");
prop = dev.get_property(propnames);
if (!prop[0].is_empty()) baud = prop[0].extractLong();
if (!prop[1].is_empty()) parity = prop[1].extractString();
if (!prop[2].is_empty()) stop = prop[2].extractShort();

// Send a write command to the device
DeviceData argin = new DeviceData();
argin.insert("Hello World!");
dev.command_inout("DevWriteMessage", argin);

// Send a read command to the device
DeviceData argout = dev.command_inout("DevReadMessage");
String received = argout.extractString();
System.out.println(received);
}
} catch (DevFailed e) {
System.out.println(e);
}
CHAPTER 2  GETTING STARTED

2.2 A C++ TANGO client

The quickest way of getting started is by studying this example:

```c++
/* 
 * example of a client using the TANGO C++ api. 
 */
#include <tango.h>
using namespace Tango;
main(unsigned int argc, char **argv) {
    // create a connection to a TANGO device
    DeviceProxy *device = new DeviceProxy("sys/database/2");
    // ping the device
    device->ping();
    // execute a command on the device and extract the reply as a string
    string db_info;
    DeviceData cmd_reply;
    cmd_reply = device->command_inout("DbInfo");
    cmd_reply >> db_info;
    cout << "command reply " << db_info << endl;
    // connect to the TANGO database
    Database *dbase = new Database();
    DbDatum sl_parity("parity"), sl_baudrate("baudrate"), sl_stopbits("stopb its");
    DbData sl_props_in, sl_props_out;
    DbDevInfo dev_info;
    DbDevExportInfo export_info;
    DbDevImportInfo import_info;
    vector<short> stopbits;
    short baudrate=19200;
    string parity("even");
    string device_name("my/serial/device");
    try {
        // get general info about the database
        cout << "dbase->get_info() : " << dbase->get_info() << endl;
        // update some device properties in the database
        sl_parity << parity;
        sl_baudrate << baudrate;
        stopbits.resize(3);
        stopbits[0] = 0;
        stopbits[1] = 1;
    } catch (...) {
        cout << "exception caught. " << exception(" ") << endl;
    }
}
```
stopbits[2] = 2;
sl_stopbits << stopbits;
sl_props_in.push_back(sl_parity);
sl_props_in.push_back(sl_baudrate);
sl_props_in.push_back(sl_stopbits);
cout << "dbase->put_device_property() called" << endl;
dbase->put_device_property(device_name, sl_props_in);

// query the database for some device properties
//
sl_props_out.push_back(DbDatum("parity"));
sl_props_out.push_back(DbDatum("baudrate"));
sl_props_out.push_back(DbDatum("stopbits"));
cout << "dbase->put_device_property(" << device_name << "") called" << endl;
dbase->get_device_property(device_name, sl_props_out);
cout << device_name;
cout << " parity - " << sl_props_out[0].value_string[0] << ",";
sl_props_out[1] >> baudrate;
cout << " baudrate - " << baudrate << ",";
sl_props_out[2] >> stopbits;
cout << " stopbits - " << stopbits.size() << endl;

// add a device to the database
//
dev_info.name = device_name;
dev_info_class = "Test";
dev_info.server = "serial/test";
cout << "dbase->add_device(" << device_name << ") called" << endl;
dbase->add_device(dev_info);

// export a device in the database
//
export_info.name = device_name;
export_info.ior = "ior";
export_info.host = "dumela";
export_info.version = "1.0";
export_info.pid = getpid();
cout << "dbase->export_device(" << device_name << ") called" << endl;
dbase->export_device(export_info);

// import a device from the database
//
cout << "dbase->import_device(" << device_name << ") called" << endl;
import_info = dbase->import_device(device_name);
cout << "info : name " << import_info.name << ",";
cout << "exported " << import_info.exported << ",";
cout << "ior " << import_info.ior << ",";
cout << "version " << import_info.version << ",";
cout << endl;
}
catch (DevFailed &e)
{
    Util::print_exception(e);
    exit(-1);
Modify this example to fit your device server or client’s needs, compile it and link with the library -tango. Forget about those painful early TANGO days when you had to learn CORBA and manipulate Any’s. Life’s going to easy and fun from now on!

## 2.3 A TANGO device server

The code given in this chapter as example has been generated using POGO. Pogo is a code generator for Tango device server. See [15] for more information about POGO. The following examples briefly describe how to write device class with commands which receives and return different kind of Tango data types and also how to write device attributes. The device class implements 5 commands and 3 attributes. The commands are:

- The command `DevSimple` deals with simple Tango data type
- The command `DevString` deals with Tango strings
- `DevArray` receive and return an array of simple Tango data type
- `DevStrArray` which does not receive any data but which returns an array of strings
- `DevStruct` which also does not receive data but which returns one of the two Tango composed types (DevVarDoubleStringArray)

For all these commands, the default behavior of the state machine (command always allowed) is acceptable. The attributes are:

- A spectrum type attribute of the Tango string type called `StrAttr`
- A readable attribute of the Tango::DevLong type called `LongRdAttr`. This attribute is linked with the following writable attribute
- A writable attribute also of the Tango::DevLong type called `LongWrAttr`.

### 2.3.1 The commands and attributes code in C++

For each command called DevXxxx, pogo generates in the device class a method named dev_xxx which will be executed when the command is requested by a client. In this chapter, the name of the device class is `DocDs`

#### 2.3.1.1 The DevSimple command

This method receives a Tango::DevFloat type and also returns a data of the Tango::DevFloat type which is simply the double of the input value. The code for the method executed by this command is the following:

```c++
1  Tango::DevFloat DocDs::dev_simple(Tango::DevFloat argin)
2  {
3      Tango::DevFloat argout;
4      DEBUG_STREAM << "DocDs::dev_simple(): entering...!" << endl;
5 ```
CHAPTER 2  GETTING STARTED

6        // Add your own code to control device here
7
8        argout = argin * 2;
9        return argout;
10    }

This method is fairly simple. The received data is passed to the method as its argument. It is
doubled at line 8 and the method simply returns the result.

2.3.1.2 The DevArray command

This method receives a data of the Tango::DevVarLongArray type and also returns a data of the
Tango::DevVarLongArray type. Each element of the array is doubled. The code for the method
executed by the command is the following:

1 Tango::DevVarLongArray *DocDs::dev_array(const Tango::DevVarLongArray *argin)
2 {
3    // POGO has generated a method core with argout allocation.
4    // If you would like to use a static reference without copying,
5    // See "TANGO Device Server Programmer’s Manual"
6    // (chapter x.x)
7    //-----------------------------------------------
8    Tango::DevVarLongArray *argout = new Tango::DevVarLongArray();
9
10    DEBUG_STREAM << "DocDs::dev_array(): entering... !" << endl;
11
12    // Add your own code to control device here
13
14    long argin_length = argin->length();
15    argout->length(argin_length);
16    for (int i = 0;i < argin_length;i++)
17        (*argout)[i] = (*argin)[i] * 2;
18
19    return argout;
20    }

The argout data array is created at line 8. Its length is set at line 15 from the input argument
length. The array is populated at line 16,17 and returned. This method allocates memory for the
argin array. This memory is freed by the Tango core classes after the data have been sent to
the caller (no delete is needed). It is also possible to return data from a statically allocated array
without copying. Look at chapter 8.2 for all the details.

2.3.1.3 The DevString command

This method receives a data of the Tango::DevString type and also returns a data of the Tango::DevString
type. The command simply displays the content of the input string and returns a hard-coded
string. The code for the method executed by the command is the following:
CHAPTER 2  GETTING STARTED

1 Tango::DevString DocDs::dev_string(Tango::DevString argin)
2 {
3     // POGO has generated a method core with argout allocation.
4     // If you would like to use a static reference without copying,
5     // See "TANGO Device Server Programmer's Manual"
6     // (chapter x.x)
7     //-----------------------------------------------
8     Tango::DevString argout;
9     DEBUG_STREAM << "DocDs::dev_string(): entering...!" << endl;
10    // Add your own code to control device here
11    cout << "the received string is " << argin << endl;
12    string str("Am I a good Tango dancer?");
13    argout = new char[str.size() + 1];
14    strcpy(argout, str.c_str());
15    return argout;
16 }

The argout string is created at line 8. Internally, this method is using a standard C++ string.
Memory for the returned data is allocated at line 16 and is initialized at line 17. This method
allocates memory for the argout string. This memory is freed by the Tango core classes after the
data have been sent to the caller (no delete is needed). It is also possible to return data from a
statically allocated string without copying. Look at chapter 8.2 for all the details.

2.3.1.4 The DevStrArray command

This method does not receive input data but returns an array of strings (Tango::DevVarStringArray
type). The code for the method executed by this command is the following:

1 Tango::DevVarStringArray *DocDs::dev_str_array()
2 {
3     // POGO has generated a method core with argout allocation.
4     // If you would like to use a static reference without copying,
5     // See "TANGO Device Server Programmer's Manual"
6     // (chapter x.x)
7     //-----------------------------------------------
8     Tango::DevVarStringArray *argout = new Tango::DevVarStringArray();
9    DEBUG_STREAM << "DocDs::dev_str_array(): entering...!" << endl;
10    // Add your own code to control device here
11    argout->length(3);
12    (*argout)[0] = CORBA::string_dup("Rumba");
13    (*argout)[1] = CORBA::string_dup("Waltz");
14    string str("Jerck");
15    (*argout)[2] = CORBA::string_dup(str.c_str());
16    return argout;
17 }

return argout;
18 }

return argout;
CHAPTER 2. GETTING STARTED

The argout data array is created at line 8. Its length is set at line 14. The array is populated at line 15,16 and 18. The last array element is initialized from a standard C++ string created at line 17. Note the usage of the string_dup function of the CORBA namespace. This is necessary for strings array due to the CORBA memory allocation schema.

2.3.1.5 The DevStruct command

This method does not receive input data but returns a structure of the Tango::DevVarDoubleStringArray type. This type is a composed type with an array of double and an array of strings. The code for the method executed by this command is the following:

```cpp
1 Tango::DevVarDoubleStringArray *DocDs::dev_struct()
2 {
3 // POGO has generated a method core with argout allocation.
4 // If you would like to use a static reference without copying,
5 // See "TANGO Device Server Programmer's Manual"
6 // (chapter x.x)
7 //-----------------------------------------------
8 Tango::DevVarDoubleStringArray *argout = new Tango::DevVarDoubleStringArray;
9
10 DEBUG_STREAM << "DocDs::dev_struct(): entering... !" << endl;
11
12 // Add your own code to control device here
13
14 argout->dvalue.length(3);
15 argout->dvalue[0] = 0.0;
16 argout->dvalue[1] = 11.11;
17 argout->dvalue[2] = 22.22;
18
19 argout->svalue.length(2);
20 argout->svalue[0] = CORBA::string_dup("Be Bop");
21 string str("Smurf");
22 argout->svalue[1] = CORBA::string_dup(str.c_str());
23
24 return argout;
25 }
```

The argout data structure is created at line 8. The length of the double array in the output structure is set at line 14. The array is populated between lines 15 and 17. The length of the string array in the output structure is set at line 19. This string array is populated between lines 20 an 22 from a hard-coded string and from a standard C++ string. This method allocates memory for the argout data. This memory is freed by the Tango core classes after the data have been sent to the caller (no delete is needed). Note the usage of the string_dup function of the CORBA namespace. This is necessary for strings array due to the CORBA memory allocation schema.

2.3.1.6 The three attributes

Some data have been added to the definition of the device class in order to store attributes value. These data are (part of the class definition) :
protected:
// Add your own data members here
// ----------------------------------
Tango::DevString attr_str_array[5];
Tango::DevLong attr_rd;
Tango::DevLong attr_wr;

One data has been created for each attribute. As the StrAttr attribute is of type spectrum with a maximum X dimension of 5, an array of length 5 has been reserved.

Several methods are necessary to implement these attributes. One method to read the hardware which is common to all "readable" attributes plus one "read" method for each readable attribute and one "write" method for each writable attribute. The code for these methods is the following:

```cpp
void DocDs::read_attr_hardware(vector<long> &attr_list)
{
    DEBUG_STREAM << "DocDs::read_attr_hardware() entering... " << endl;
    // Add your own code here
    string att_name;
    for (long i = 0; i < attr_list.size(); i++)
    {
        att_name = dev_attr->get_attr_by_ind(attr_list[i]).get_name();
        if (att_name == "LongRdAttr")
        {
            attr_rd = 5;
        }
    }
}

void DocDs::read_LongRdAttr(Tango::Attribute &attr)
{
    DEBUG_STREAM << "DocDs::read_LongRdAttr() entering... " << endl;
    attr.set_value(&attr_rd);
}

void DocDs::read_LongWrAttr(Tango::Attribute &attr)
{
    DEBUG_STREAM << "DocDs::read_LongWrAttr() entering... " << endl;
    attr.set_value(&attr_wr);
}

void DocDs::write_LongWrAttr(Tango::WAttribute &attr)
{
    DEBUG_STREAM << "DocDs::write_LongWrAttr() entering... " << endl;
```
CHAPTER 2  GETTING STARTED

35   attr.get_write_value(attr_wr);
36   DEBUG_STREAM << "Value to be written - " << attr_wr << endl;
37 }
38 }
39 void DocDs::read_StrAttr(Tango::Attribute &attr)
40 {
41   DEBUG_STREAM << "DocDs::read_StrAttr() entering... " << endl;
42   attr_str_array[0] = CORBA::string_dup("Rock");
43   attr_str_array[1] = CORBA::string_dup("Samba");
44   attr_set_value(attr_str_array, 2);
45 }

The read_attr_hardware() method is executed once when a client execute the read_attributes CORBA request whatever the number of attribute to be read is. The rule of this method is to read the hardware and to store the read values somewhere in the device object. In our example, only the LongRdAttr attribute internal value is set by this method at line 13. The method read_LongRdAttr() is executed by the read_attributes CORBA call when the LongRdAttr attribute is read but after the read_attr_hardware() method has been executed. Its rule is to set the attribute value in the TANGO core classes object representing the attribute. This is done at line 22. The method read_LongWrAttr() will be executed when the LongWrAttr attribute is read (after the read_attr_hardware() method). The attribute value is set at line 29. In the same manner, the method called read_StrAttr() will be executed when the attribute StrAttr is read. Its value is initialized in this method at line 44 and 45 with the string_dup CORBA function. The write_LongWrAttr() method is executed when the LongWrAttr attribute value is set by a client. The new attribute value coming from the client is stored in the object data at line 36.

Pogo also generates a file called "DocDsStateMachine.cpp" (for a Tango device server class called DocDs). This file is used to store methods coding the device state machine. By default a always allowed state machine is provided. For more information about coding the state machine, refer to the chapter "Writing a device server".

2.3.2 The commands and attributes code in java

For each command called DevXxxx, pogo generates in the device class a method named dev_xxxx which will be executed when the command is requested by a client. In this chapter, the name of the device class is DocDs

2.3.2.1 The DevSimple command

This method receives a Tango DevFloat type and also returns a data of the Tango DevFloat type which is simply the double of the input value. Using java, the Tango::DevFloat type is mapped to classical java float type. The code for the method executed by this command is the following:

1 public float dev_simple(float argin) throws DevFailed
2 {
3     float argout = (float)0;
4     Util.out2.println("Entering dev_simple()");
5 }
CHAPTER 2  GETTING STARTED

7  // ---Add your Own code to control device here ---
8 9  argout = argin * 2;
10  return argout;
11 }

This method is fairly simple. The received data is passed to the method as its argument. It is doubled at line 9 and the method simply returns the result.

2.3.2.2 The DevArray command

This method receives a data of the Tango::DevVarLongArray type and also returns a data of the Tango::DevVarLongArray type. Each element of the array is doubled. Using java, the Tango DevVarLongArray type is mapped to an array of java long. The code for the method executed by the command is the following:

1  public int[] dev_array(int[] argin) throws DevFailed
2  {
3     int[] argout = new int[argin.length];
4     5     Util.out2.println("Entering dev_array()");
6     // ---Add your Own code to control device here ---
7 8     for (int i = 0; i < argin.length;i++)
9         argout[i] = argin[i] * 2;
10     return argout;
11 }

The argout data array is created at line 3. The array is populated at line 9,10 and returned.

2.3.2.3 The DevString command

This method receives a data of the Tango DevString type and also returns a data of the Tango DevString type. The command simply displays the content of the input string and returns a hard-coded string. Using java, the Tango DevString type simply maps to java String. The code for the method executed by the command is the following:

1  public String dev_string(String argin) throws DevFailed
2  {
3     Util.out2.println("Entering dev_string()");
4     // ---Add your Own code to control device here ---
5 6     System.out.println("the received string is "+argin);
7 8     String argout = new String("Am I a good Tango dancer ?");
9     return argout;
10 }

The argout string is created at line 9.

### 2.3.2.4 The DevStrArray command

This method does not receive input data but returns an array of strings (Tango DevVarStringArray type). Using java, the Tango DevVarStringArray type maps to an array of java String. The code for the method executed by this command is the following:

```java
1  public String[] dev_str_array() throws DevFailed
2  {
3       Util.out2.println("Entering dev_str_array()");
4       // ---Add your Own code to control device here ---
5     String[] argout = new String[3];
6       argout[0] = new String("Rumba");
7       argout[1] = new String("Waltz");
8       argout[2] = new String("Jerck");
9            return argout;
10  }
```

The argout data array is created at line 8. The array is populated at line 9,10 and 11.

### 2.3.2.5 The DevStruct command

This method does not receive input data but returns a structure of the Tango DevVarDoubleStringArray type. This type is a composed type with an array of double and an array of strings. This is mapped to a specific java class called DevVarDoubleStringArray. The code for the method executed by this command is the following:

```java
1  public DevVarDoubleStringArray dev_struct() throws DevFailed
2  {
3       DevVarDoubleStringArray argout = new DevVarDoubleStringArray();
4            Util.out2.println("Entering dev_struct()");
5       // ---Add your Own code to control device here ---
6     argout.dvalue = new double[3];
7       argout.dvalue[0] = 0.0;
8       argout.dvalue[1] = 11.11;
9       argout.dvalue[2] = 22.22;
10      argout.svalue = new String[2];
11      argout.svalue[0] = new String("Be Bop");
12      argout.svalue[1] = new String("Smurf");
13      return argout;
14  }
```
The argout data structure is created at line 3. The double array in the output structure is created at line 9. The array is populated between lines 10 and 12. The string array in the output structure is created at line 14. This string array is populated between lines 15 and 16 from hard-coded strings.

2.3.2.6 The three attributes
Some data have been added to the definition of the device class in order to store attributes value. These data are (part of the class definition):

```java
1 protected String[] attr_str_array = new String[5];
2 protected int attr_rd;
3 protected int attr_wr;
```

One data has been created for each attribute. As the StrAttr attribute is of type spectrum with a maximum X dimension of 5, an array of length 5 has been reserved.

Unfortunately, Java Tango device server are not at the same level of development than C++ device servers. This is why they are not written exactly the same way than C++ device servers. Three methods are necessary to implement these attributes. The code for these methods is the following:

```java
1 public void write_attr_hardware(Vector attr_list)
2 {
3     Util.out2.println("In write_attr_hardware for "+attr_list.size()+" attribute
4     for (int i=0 ; i<attr_list.size() ; i++)
5         {
6             int ind = ((Integer)(attr_list.elementAt(i))).intValue();
7             WAttribute att = dev_attr.get_w_attr_by_ind(ind);
8             String attr_name = att.get_name();
9         }
10         // Switch on attribute name
11         //-------------------------------
12         if (attr_name.equals("LongWrAttr") == true)
13             {
14                 // Add your own code here
15                 attr_wr = att.get_lg_write_value();
16                 System.out.println("Value to be written - "+attr_wr);
17             }
18     }
19 }
20 }
21
22 public void read_attr_hardware(Vector attr_list)
23 {
24     Util.out2.println("In read_attr_hardware for "+attr_list.size()+" attribute(}
25     for (int i=0 ; i<attr_list.size() ; i++)
26         {
27             int ind = ((Integer)(attr_list.elementAt(i))).intValue();
28             WAttribute att = dev_attr.get_w_attr_by_ind(ind);
29             String attr_name = att.get_name();
30             String attr_value = att.get_lg_read_value();
31             System.out.println("Value to be read - "+attr_value);
32         }
33     }
34 }
35 public void delete_attr_hardware()
36 {
37     // Add your own code here
38     System.out.println("Deleting attributes");
39 }
40 ```
27     // Add you own code here
28     //----------------------------------------
29     for (int i=0; i<attr_list.size(); i++)
30     {
31         int ind = ((Integer)(attr_list.elementAt(i))).intValue();
32     Attribute att = dev_attr.get_attr_by_ind(ind);
33     String attr_name = attr_list.elementAt(i);
34     if (attr_name.equals("LongRdAttr") -- true)
35     {
36         attr_rd = 5;
37     }
38     else if (attr_name.equals("StrAttr") -- true)
39     {
40         attr_str_array[0] = new String("Rock");
41         attr_str_array[1] = new String("Samba");
42     }
43     }
44     }
45     }
46     }
47     }
48     }
49     public void read_attr(Attribute attr) throws DevFailed
50     {
51         String attr_name = attr.get_name();
52         Util.out2.println("In read_attr for attribute "+attr_name);
53     // Switch on attribute name
54     //----------------------------------------
55     if (attr_name.equals("LongWrAttr") -- true)
56     {
57         // Add you own code here
58         attr.set_value(attr_wr);
59     }
60     if (attr_name.equals("LongRdAttr") -- true)
61     {
62         // Add you own code here
63         attr.set_value(attr_rd);
64     }
65     if (attr_name.equals("StrAttr") -- true)
66     {
67         // Add you own code here
68         attr.set_value(attr_str_array);
69     }
70     }
71     }

The write_attr_hardware() method is executed when an attribute value is set by a client. In our example only one attribute is writable (the LongWrAttr attribute). The new attribute value coming from the client is stored in the object data at line 16. The read_attr_hardware() method is executed once when a client execute the read_attributes CORBA request. The rule of this method is to read the hardware and to store the read values somewhere in the device object. In our example, the LongRdAttr attribute internal value is set by this method at line 38 at the
StrAttr attribute internal value is set at lines 42 and 43. The method \texttt{read\_attr()} is executed for each attribute to be read by the \texttt{read\_attributes} CORBA call. Its rule is to set the attribute value in the TANGO core classes object representing the attribute. This is done at line 64 for the \texttt{LongRdAttr} attribute, at line 59 for the \texttt{LongWrAttr} attribute and at line 69 for the \texttt{StrAttr} attribute.
Chapter 3

The TANGO device server model

This chapter will present the TANGO device server object model hereafter referred as TDSOM. First, it will introduce CORBA. Then, it will describe each of the basic features of the TDSOM and their function. The TDSOM can be divided into the following basic elements - the device, the server, the database and the application programmers interface. This chapter will treat each of the above elements separately.

3.1 Introduction to CORBA

CORBA is a definition of how to write object request brokers (ORB). The definition is managed by the Object Management Group (OMG [1]). Various commercial and non-commercial implementations exist for CORBA for all the mainstream operating systems. CORBA uses a programming language independent definition language (called IDL) to defined network object interfaces. Language mappings are defined from IDL to the main programming languages e.g. C++, Java, C, COBOL, Smalltalk and ADA. Within an interface, CORBA defines two kinds of actions available to the outside world. These actions are called attributes and operations.

Operations are all the actions offered by an interface. For instance, within an interface for a Thermostat class, operations could be the action to read the temperature or to set the nominal temperature. An attribute defines a pair of operations a client can call to send or receive a value. For instance, the position of a motor can be defined as an attribute because it is a data that you only set or get. A read only attribute defines a single operation the client can call to receive a value. In case of error, an operation is able to throw an exception to the client, attributes cannot raise exception except system exception (due to network fault for instance).

Intuitively, IDL interface correspond to C++ classes and IDL operations correspond to C++ member functions and attributes as a way to read/write public member variable. Nevertheless, IDL defines only the interface to an object and say nothing about the object implementation. IDL is only a descriptive language. Once the interface is fully described in the IDL language, a compiler (from IDL to C++, from IDL to Java...) generates code to implement this interface. Obviously, you still have to write how operations are implemented.

The act of invoking an operation on an interface causes the ORB to send a message to the corresponding object implementation. If the target object is in another address space, the ORB run time sends a remote procedure call to the implementation. If the target object is in the same address space as the caller, the invocation is accomplished as an ordinary function call to avoid the overhead of using a networking protocol.

For an excellent reference on CORBA with C++ refer to [2]. The complete TANGO IDL file can be found in the TANGO web page[3] or at the end of this document in the appendix 2 chapter.
CHAPTER 3. THE TANGO DEVICE SERVER MODEL

3.2 The model

The basic idea of the TDSOM is to treat each device as an object. Each device is a separate entity which has its own data and behavior. Each device has a unique name which identifies it in network name space. Devices are organized according to classes, each device belonging to a class. All classes are derived from one root class thus allowing some common behavior for all devices. Four kind of requests can be sent to a device (locally i.e. in the same process, or remotely i.e. across the network):

- Execute actions via commands
- Read/Set data specific to each device belonging to a class via TANGO attributes
- Read some basic device data available for all devices via CORBA attributes.
- Execute a predefined set of actions available for every devices via CORBA operations

Each device is stored in a process called a device server. Devices are configured at runtime via properties which are stored in a database.

3.3 The device

The device is the heart of the TDSOM. A device is an abstract concept defined by the TDSOM. In reality, it can be a piece of hardware (an interlock bit) a collection of hardware (a screen attached to a stepper motor) a logical device (a taper) or a combination of all these (an accelerator). Each device has a unique name in the control system and eventually one alias. Within Tango, a four field name space has been adopted consisting of

```
//FACILITY/]DOMAIN/CLASS/MEMBER
```

Facility refers to the control system instance, domain refers to the sub-system, class the class and member the instance of the device. Device name alias(es) must also be unique within a control system. There is no predefined syntax for device name alias.

Each device belongs to a class. The device class contains a complete description and implementation of the behavior of all members of that class. New device classes can be constructed out of existing device classes. This way a new hierarchy of classes can be built up in a short time. Device classes can use existing devices as sub-classes or as sub-objects. The practice of reusing existing classes is classical for Object Oriented Programming and is one of its main advantages.

All device classes are derived from the same class (the device root class) and implement the same CORBA interface. All devices implementing the same CORBA interface ensures all control object support the same set of CORBA operations and attributes. The device root class contains part of the common device code. By inheriting from this class, all devices shared a common behavior. This also makes maintenance and improvements to the TDSOM easy to carry out.

All devices also support a black box where client requests for attributes or operations are recorded. This feature allows easier debugging session for device already installed in a running control system.

3.3.1 The commands

Each device class implements a list of commands. Commands are very important because they are the client's major dials and knobs for controlling a device. Commands have a fixed calling syntax - consisting of one input argument and one output argument. Arguments type must be chosen in a fixed set of data types: All simple types (boolean, short, long, float, double, unsigned short, unsigned long string) and arrays of simple types plus array of strings and longs and array of strings and doubles). Commands can execute any sequence of actions. Commands can be
executed synchronously (the requester is blocked until the command ended) or asynchronously
(the requester sends the request and is called back when the command ended).

Commands are executed using two CORBA operations named \texttt{command\_inout} for syn-
chronous commands and \texttt{command\_inout\_async} for asynchronous commands. These two
operations called a special method implemented in the device root class - the \texttt{command\_handler}
method. The \texttt{command\_handler} calls an \texttt{is\_allowed} method implemented in the device class be-
fore calling the command itself. The \texttt{is\_allowed} method is specific to each command\(^1\). It checks
to see whether the command to be executed is compatible with the present device state. The
command function is executed only if the \texttt{is\_allowed} method allows it. Otherwise, an exception
is sent to the client.

\subsection{The TANGO attributes}

In addition to commands, TANGO devices also support normalized data types called attributes\(^2\). Commands are device specific and the data they transport are not normalized i.e. they can be
any one of the TANGO data types with no restriction on what each byte means. This means that
it is difficult to interpret the output of a command in terms of what kind of value(s) it represents.
Generic display programs need to know what the data returned represents, in what units it is, plus
additional information like minimum, maximum, quality etc. TANGO attributes solve this problem.

TANGO attributes are zero, one or two dimensional data which have a fix set of properties
e.g. quality, minimum and maximum, alarm low and high. They are transferred in a specialized
TANGO type and can be read, write or read-write. A device can support a list of attributes.
Clients can read one or more attributes from one or more devices. To read TANGO attributes,
the client uses the \texttt{read\_attributes} operation. To write TANGO attributes, a client uses the
\texttt{write\_attributes} operation. To query a device for all the attributes it supports, a client uses the
\texttt{get\_attribute\_config} operation. A client is also able to modify some of parameters defining
an attribute with the \texttt{set\_attribute\_config} operation. These four operations are defined in the
device CORBA interface.

TANGO support eight data types for attributes (and arrays of for one or two dimensional
data) which are: boolean, short, long, float, double, unsigned char, unsigned short and string.

\subsection{Command or attributes ?}

There are no strict rules concerning what should be returned as command result and what should
be implemented as an attribute. Nevertheless, attributes are more adapted to return physical
value which have a kind of time consistency. Attribute also have more properties which help the
client to precisely know what it represents. For instance, the state and the status of a power supply
are not physical values and are returned as command result. The current generated by the power
supply is a physical value and is implemented as an attribute. The attribute properties allow a
client to know its unit, its label and some other informations which are related to a physical value.
Command are well adapted to send order to a device like switching from one mode of operation
to another mode of operation. For a power supply, the switch from a STANDBY mode to a ON
mode is typically done via a command.

\subsection{The CORBA attributes}

Some key data implemented for each device can be read without the need to call a command or
read an attribute. These data are:

- The device state
- The device status

\footnotesize
\(^1\)In contrary to the \texttt{state\_handler} method of the TACO device server model which is not specific to each
command.
\(^2\)TANGO attributes were known as signals in the TACO device server model
CHAPTER 3. THE TANGO DEVICE SERVER MODEL

- The device name
- The administration device name called adm_name
- The device description

The device state is a number representing its state. A set of predefined states are defined in the TDSOM. The device status is a string describing in plain text the device state and any additional useful information of the device as a formatted ascii string. The device name is its name as defined in 3.3. For each set of devices grouped within the same server, an administration device is automatically added. This adm_name is the name of the administration device. The device description is also an ascii string describing the device rule.

These five CORBA attributes are implemented in the device root class and therefore do not need any coding from the device class programmer. As explained in 3.1, the CORBA attributes are not allowed to raise exceptions whereas command (which are implemented using CORBA operations) can.

3.3.5 The remaining CORBA operations

The TDSOM also supports a list of actions defined as CORBA operations in the device interface and implemented in the device root class. Therefore, these actions are implemented automatically for every TANGO device. These operations are:

ping to ping a device to check if the device is alive. Obviously, it checks only the connection from a client to the device and not all the device functionalities

command_list_query request a list of all the commands supported by a device with their input and output types and description

command_query request information about a specific command which are its input and output type and description

info request general information on the device like its name, the host where the device server hosting the device is running...

black_box read the device black-box as an array of strings

3.3.6 The special case of the device state and status

Device state and status are the most important key device informations. Nearly all client software dealing with Tango device needs device(s) state and/or status. In order to simplify client software developer work, it is possible to get these two piece of information in three different manners:

1. Using the appropriate CORBA attribute (state or status)
2. Using command on the device. The command are called State or Status
3. Using attribute. Even if the state and status are not real attribute, it is possible to get their value using the read_attributes operation. Nevertheless, it is not possible to set the attribute configuration for state and status. An error is reported by the server if a client try to do so.
3.3.7 The device polling

Within the Tango framework, it is also possible to force executing command(s) or reading attribute(s) at a fixed frequency. It is called device polling. This is automatically handled by Tango core software with a polling thread. The command result or attribute value are stored in circular buffers. When a client want to read attribute value (or command result) for a polled attribute (or a polled command), he has the choice to get the attribute value (or command result) with a real access to the device of from the last value stored in the device ring buffer. This is a great advantage for “slow” devices. Getting data from the buffer is much faster than accessing the device itself. The technical disadvantage is the time shift between the data returned from the polling buffer and the time of the request. Polling a command is only possible for command without input arguments.

Two other CORBA operations called command_inout_history_2 and read_attribute_history_2 allow a client to retrieve the history of polled command or attribute stored in the polling buffers. Obviously, this history is limited to the depth of the polling buffer.

The whole polling system is available only since Tango release 2.x and above in CPP and since TangORb release 3.7.x and above in Java.

3.4 The server

Another integral part of the TDSOM is the server concept. The server (also referred as device server) is a process whose main task is to offer one or more services to one or more clients. To do this, the server has to spend most of its time in a wait loop waiting for clients to connect to it. The devices are hosted in the server process. A server is able to host several classes of devices. In the TDSOM, a device of the DServer class is automatically hosted by each device server. This class of device supports commands which enable remote device server process administration.

TANGO supports device server process on three operating system : Linux, Solaris and Windows NT.

3.5 The Tango Logging Service

During software life, it is always convenient to print miscellaneous informations which help to:

- Debug the software
- Report on error
- Give regular information to user

This is classically done using cout (or C printf) in C++ or println method in Java language. In a highly distributed control system, it is difficult to get all these informations coming from a high number of different processes running on a large number of computers. Since its release 3, Tango has incorporated a Logging Service called the Tango Logging Service (TLS) which allows print messages to be:

- Displayed on a console (the classical way)
- Sent to a file
- Sent to specific Tango device called log consumer. Tango package has an implementation of log consumer where every consumer device is associated to a graphical interface. This graphical interface display messages but could also be used to sort messages, to filter messages... Using this feature, it is possible to centralise display of these messages coming from different devices embedded within different processes. These log consumers can be:
3.6 The database

To achieve complete device independence, it is necessary however to supplement device classes with a possibility for configuring device dependencies at runtime. The utility which does this in the TDSOM is the **property database**. Properties\(^3\) are identified by an ascii string and the device name. TANGO attributes are also configured using properties. This database is also used to store device network addresses (CORBA IOR's), list of classes hosted by a device server process and list of devices for each class in a device server process. The database ensure the uniqueness of device name and of alias. It also links device name and it list of aliases.

TANGO uses MySQL[6] as its database. MySQL is a relational database which implements a subset of the SQL language. However, this subset is enough to implement all the functionalities needed by the TDSOM. The database is accessed via a classical TANGO device hosted in a device server. Therefore, client access the database via TANGO commands requested on the database device. For a good reference on MySQL refer to [7]

3.7 The Application Programmers Interfaces

3.7.1 Rules of the API

While it is true TANGO clients can be programmed using only the CORBA API, CORBA knows nothing about TANGO. This means client have to know all the details of retrieving IORs from the TANGO database, additional information to send on the wire, TANGO version control etc. These details can and should be wrapped in TANGO Application Programmer Interface (API). The API is implemented as a library in C++ and as a package in Java. The API is what makes TANGO clients easy to write. The API's consists the following basic classes:

- DeviceProxy which is a *proxy* to the real device
- DeviceData to encapsulate data send/receive from/to device via commands
- DeviceAttribute to encapsulate data send/receive from/to device via attributes
- Group which is a *proxy* to a group of devices

In addition to these main classes, many other classes allows a full interface to TANGO features. The following figure is a drawing of a typical client/server application using TANGO.

\(^3\)Properties were known as resources in the TACO device server model
The database is used during server and client startup phase to establish connection between client and server.

3.7.2 Communication between client and server using the API

With the API, it is possible to request command to be executed on a device or to read/write device attribute(s) using one of the two communication models implemented. These two models are:

1. The synchronous model where client waits (and is blocked) for the server to send the answer or until the timeout is reached

2. The asynchronous model. In this model, the clients send the request and immediately returns. It is not blocked. It is free to do whatever it has to do like updating a graphical user interface. The client has the choice to retrieve the server answer by checking if the reply is arrived by calling an API specific call or by requesting that a call-back method is executed when the client receives the server answer.

The asynchronous model is available with Tango release 3 and above.

3.7.3 Tango events

On top of the two communication model previously described, TANGO offers an "event system". The standard TANGO communication paradigm is a synchronous/asynchronous two-way call. In this paradigm the call is initiated by the client who contacts the server. The server handles the client's request and sends the answer to the client or throws an exception which the client catches. This paradigm involves two calls to receive a single answer and requires the client to be active in initiating the request. If the client has a permanent interest in a value he is obliged to poll the server for an update in a value every time. This is not efficient in terms of network bandwidth nor in terms of client programming.

For clients who are permanently interested in values the event-driven communication paradigm is a more efficient and natural way of programming. In this paradigm the client registers her interest once in an event (value). After that the server informs the client every time the event has occurred. This paradigm avoids the client polling, frees it for doing other things, is fast and makes efficient use of the network.
TANGO uses the CORBA OMG COS Notification Service to generates events. TANGO uses the omniNotify implementation of the Notification service. omniNotify was developed in conjunction with the omniORB CORBA implementation also used by TANGO. The heart of the Notification Service is the notification daemon. The omniNotify daemons are the processes which receive events from device servers and distribute them to all clients which are subscribed. In order to distribute the load of the events there is one notification daemon per host. Servers send their events to the daemon on the local host. Clients and servers get the IOR for the host from the TANGO database.

The following figure is a schematic of the Tango event system.

**Schematic of TANGO Events system**

The event system is available with Tango release 4 and above
Chapter 4

Writing a TANGO client using TANGO APIs

4.1 Introduction

TANGO devices and database are implemented using the TANGO device server model. To access them the user has the CORBA interface e.g. command_inout(), write_attributes() etc. defined by the idl file. These methods are very low-level and assume a good working knowledge of CORBA. In order to simplify this access, high-level api in C++ and Java have been implemented which hides all CORBA aspects of TANGO. In addition the api hides details like how to connect to a device via the database, how to reconnect after a device has been restarted, how to correctly pack and unpack attributes and so on by implementing these in a manner transparent to the user. The api provides a unified error handling for all TANGO and CORBA errors. Unlike the CORBA C++ bindings the TANGO api supports native C++ data types e.g. strings and vectors.

This chapter describes how to use these API's. It is not a reference guide. See chapter 6 for the C++ API details or chapter 5 for a Java API reference guide.

4.2 Getting Started

Refer to the chapter "Getting Started" for an example on getting start with the C++ or Java api.

4.3 Basic Philosophy

The basic philosophy is to have high level classes to deal with Tango devices. To communicate with Tango device, uses the DeviceProxy class. To send/receive data to/from Tango device, uses the DeviceData or DeviceAttribute classes. To communicate with a group of devices, use the Group class. If you are interested only in some attributes provided by a Tango device, uses the AttributeProxy class. Even if the Tango database is implemented as any other devices (and therefore accessible with one instance of a DeviceProxy class), specific high level classes have been developed to query it. Uses the Database, DbDevice, DbClass, DbServer or DbData classes when interfacing the Tango database. Callback for asynchronous requests or events are implemented via a CallBack class. An utility class called ApiUtil is also available.

4.4 Request model

For the most important API remote calls (command_inout, read_attribute(s) and write_attribute(s)), Tango supports two kind of requests which are the synchronous model and the asynchronous model.
Synchronous model means that the client waits (and is blocked) for the server to send an answer. Asynchronous model means that the client does not wait for the server to send an answer. The client sends the request and immediately returns allowing the CPU to do anything else (like updating a graphical user interface). Within Tango, there are two ways to retrieve the server answer when using asynchronous model. They are:

1. The polling mode
2. The callback mode

In polling mode, the client executes a specific call to check if the answer is arrived. If this is not the case, an exception is thrown. If the reply is there, it is returned to the caller and if the reply was an exception, it is re-thrown. There are two calls to check if the reply is arrived:

- Call which does not wait before the server answer is returned to the caller.
- Call which wait with timeout before returning the server answer to the caller (or throw the exception) if the answer is not arrived.

In callback model, the caller must supply a callback method which will be executed when the command returns. They are two sub-modes:

1. The pull callback mode
2. The push callback mode

In the pull callback mode, the callback is triggered if the server answer is arrived when the client decide it by calling a synchronization method (the client pull-out the answer). In push mode, the callback is executed as soon as the reply arrives in a separate thread (the server pushes the answer to the client).

Note: The C++ DeviceProxy class is **not thread safe**. The user must take care if some action using DeviceProxy instances are programmed within the call-back methods in case of multi-threaded application.

### 4.4.1 Synchronous model

Synchronous access to Tango device are provided using the DeviceProxy or AttributeProxy class. For the DeviceProxy class, the main synchronous call methods are:

- `command_inout()` to execute a Tango device command
- `read_attribute()` or `read_attributes()` to read a Tango device attribute(s)
- `write_attribute()` or `write_attributes()` to write a Tango device attribute

For commands, data are send/received to/from device using the DeviceData class. For attributes, data are send/received to/from device attribute using the DeviceAttribute class.

In some cases, only attributes provided by a Tango device are interesting for the application. You can use the AttributeProxy class. Its main synchronous methods are:

- `read()` to read the attribute value
- `write()` to write the attribute value

Data are transmitted using the DeviceAttribute class.
4.4.2 Asynchronous model

Asynchronous access to Tango device are provided using DeviceProxy or AttributeProxy, CallBack and ApiUtil classes methods. The main asynchronous call methods and used classes are:

- To execute a command on a device
  - DeviceProxy::command_inout_asynch() and DeviceProxy::command_inout_reply() in polling model.
  - DeviceProxy::command_inout_asynch(), DeviceProxy::get_asynch_replies() and CallBack class in callback pull model
  - DeviceProxy::command_inout_asynch(), ApiUtil::set_asynch_cb_sub_model() and CallBack class in callback push model

- To read a device attribute
  - DeviceProxy::read_attribute_asynch() and DeviceProxy::read_attribute_reply() in polling model
  - DeviceProxy::read_attribute_asynch(), DeviceProxy::get_asynch_replies() and CallBack class in callback pull model
  - DeviceProxy::read_attribute_asynch(), ApiUtil::set_asynch_cb_sub_model() and CallBack class in callback push model

- To write a device attribute
  - DeviceProxy::write_attribute_asynch() in polling model
  - DeviceProxy::write_attribute_asynch() and CallBack class in callback pull model
  - DeviceProxy::write_attribute_asynch(), ApiUtil::set_asynch_cb_sub_model() and CallBack class in callback push model

For commands, data are send/received to/from device using the DeviceData class. For attributes, data are send/received to/from device attribute using the DeviceAttribute class. It is also possible to generate asynchronous request(s) using the AttributeProxy class following the same schema than above. Methods to use are:

- read_asynch() and read_reply() to asynchronously read the attribute value
- write_asynch() and write_reply() to asynchronously write the attribute value

4.5 Events

4.5.1 Introduction

Events are a critical part of any distributed control system. Their aim is to provide a communication mechanism which is fast and efficient.

The standard CORBA communication paradigm is a synchronous or asynchronous two-way call. In this paradigm the call is initiated by the client who contacts the server. The server handles the client's request and sends the answer to the client or throws an exception which the client catches. This paradigm involves two calls to receive a single answer and requires the client to be active in initiating the request. If the client has a permanent interest in a value he is obliged to poll the server for an update in a value every time. This is not efficient in terms of network bandwidth nor in terms of client programming.

For clients who are permanently interested in values the event-driven communication paradigm is a more efficient and natural way of programming. In this paradigm the client registers her
interest once in an event (value). After that the server informs the client every time the event has occurred. This paradigm avoids the client polling, frees it for doing other things, is fast and makes efficient use of the network.

The rest of this chapter explains how the TANGO events are implemented and the application programmer's interface.

4.5.2 Event definition

TANGO events represent an alternative channel for reading TANGO device attributes. Device attributes values are sent to all subscribed clients when an event like change in a device attribute value, quality change, periodically occurs. The clients continue receiving events as long as they stay subscribed. Most of the time, the device server polling thread detects the event and then pushes the device attribute value to all clients. Nevertheless, in some cases, the delay introduced by the polling thread in the event propagation is detrimental. For such cases, some API calls directly push the event. The omniNotify implementation of the CORBA Notification service is used to dispatch events.

4.5.3 Event types

The following five event types have been implemented in TANGO:

1. change - an event is triggered and the attribute value is sent when the attribute value changes significantly. The exact meaning of significant is device attribute dependant. For analog and digital values this is a delta fixed per attribute, for string values this is any non-zero change i.e. if the new attribute value is not equal to the previous attribute value. The delta can either be specified as a relative or absolute change. The delta is the same for all clients unless a filter is specified (see below). To easily write applications using the change event, it is also triggered in the following case:

   (a) When a spectrum or image attribute size changes.
   (b) At event subscription time
   (c) When the polling thread receives an exception during attribute reading
   (d) When the polling thread detect that the attribute quality factor has changed to INVALID
   (e) The first good reading of the attribute after the polling thread has received exception when trying to read the attribute
   (f) The first time the polling thread detect that the attribute quality factor has changed from INVALID to something else

2. quality - an event is triggered and the attribute value is sent if the attribute quality factor changes e.g. from valid to alarm or vice versa. The event is also triggered in the following case:

   (a) At event subscription time
   (b) When the polling thread receives an exception during attribute reading
   (c) The first good reading of the attribute after the polling thread has received exception when trying to read the attribute
   (d) By the methods Attribute::set_quality() and Attribute::set_value_date_quality() if a client has subscribed to the quality change event on the attribute. This has been implemented for cases where the delay introduced by the polling thread in the event propagation is not authorized.
3. **periodic** - an event is sent at a fixed periodic interval. The frequency of this event is determined by the `event_period` property of the attribute and the polling frequency. The polling frequency determines the highest frequency at which the attribute is read. The `event_period` determines the highest frequency at which the periodic event is sent. Note if the `event_period` is not an integral number of the polling period there will be a beating of the two frequencies\(^1\). Clients can reduce the frequency at which they receive periodic events by specifying a filter on the periodic event counter.

4. **archive** - an event is sent if one of the archiving conditions is satisfied. Archiving conditions are defined via properties in the database. These can be a mixture of `delta_change` and periodic.

5. **user** - The criteria and configuration of these user events are managed by the device server programmer who uses a specific method of one of the Tango device server class to fire the event (`DeviceImpl:push_event()`).

The first four above events are automatically generated by the TANGO device server library.

### 4.5.4 Event filtering

The CORBA Notification Service allows event filtering. This means that a client can ask the Notification Service to send the event only if some filter is evaluated to true. Within the Tango control system, some pre-defined fields can be used as filter. These fields depend on the event type.

<table>
<thead>
<tr>
<th>Event type</th>
<th>Filterable field name</th>
<th>Filterable field value</th>
<th>type</th>
</tr>
</thead>
<tbody>
<tr>
<td>change</td>
<td><code>delta_rel_change</code></td>
<td>Relative change (in %) since last event</td>
<td>double</td>
</tr>
<tr>
<td></td>
<td><code>delta_abs_change</code></td>
<td>Absolute change since last event</td>
<td>double</td>
</tr>
<tr>
<td>periodic</td>
<td><code>counter</code></td>
<td>Incremented each time the event is sent</td>
<td>long</td>
</tr>
<tr>
<td></td>
<td><code>delta_rel_change</code></td>
<td>Relative change (in %) since last event</td>
<td>double</td>
</tr>
<tr>
<td></td>
<td><code>delta_abs_change</code></td>
<td>Absolute change since last event</td>
<td>double</td>
</tr>
<tr>
<td>archive</td>
<td><code>counter</code></td>
<td>Incremented each time the event is sent</td>
<td>long</td>
</tr>
<tr>
<td></td>
<td></td>
<td>for periodic reason. Set to -1 if event</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>sent for change reason</td>
<td></td>
</tr>
</tbody>
</table>

Filter are defined as a string following a grammar defined by CORBA. It is defined in [18]. The following example shows you the most common use of these filters in the Tango world:

- To receive periodic event one out of every three, the filter must be
  \[
  \$\text{counter \% 3 == 0}
  \]

- To receive change event only if the relative change is greater than 20 % (positive and negative), the filter must be
  \[
  \$\text{rel_change} >= 20 \text{ or } \$\text{rel_change} <= -20
  \]

For user events, the filter field name(s) and their value are defined by the device server programmer.

\(^1\text{note: the polling is not synchronised is currently not synchronised on the hour}\)
4.5.5 Application Programmer’s Interface

How to setup and use the TANGO events? The interfaces described here are intended as user-friendly interfaces to the underlying CORBA calls. The interface is modelled after the asynchronous `command_inout()` interface so as to maintain coherency. The event system supports only one type of request model which is the **push callback model**.

4.5.5.1 Configuring events

The attribute configuration set is used to configure under what conditions events are generated. A set of standard attribute properties (part of the standard attribute configuration) are read from the database at device startup time and used to configure the event engine. If there are no properties defined then default values specified in the code are used.

4.5.5.1.1 change

The attribute properties and their default values for the "change" event are:

1. **rel_change** - a property of maximum 2 values. It specifies the positive and negative relative change of the attribute value w.r.t. the value of the previous change event which will trigger the event. If the attribute is a spectrum or an image then a change event is generated if any one of the attribute value's satisfies the above criterion. If only one property is specified then it is used for the positive and negative change.

2. **abs_change** - a property of maximum 2 values. It specifies the positive and negative absolute change of the attribute value w.r.t. the value of the previous change event which will trigger the event. If the attribute is a spectrum or an image then a change event is generated if any one of the attribute value's satisfies the above criterion. If only one property is specified then it is used for the positive and negative change. If no properties are specified then the relative change is used.

4.5.5.1.2 periodic

The attribute properties and their default values for the "periodic" event are:

1. **event_period** - the minimum time between events (in milliseconds). If no property is specified then a default value of 1 second is used.

4.5.5.1.3 archive

The attribute properties and their default values for the "archive" event are:

1. **archive_rel_change** - a property of maximum 2 values which specifies the positive and negative relative change w.r.t. the previous attribute value which will trigger the event. If the attribute is a spectrum or an image then an archive event is generated if any one of the attribute value's satisfies the above criterion. If only one property is specified then it is used for the positive and negative change. If no properties are specified then a default of +10% is used.

2. **archive_abs_change** - a property of maximum 2 values which specifies the positive and negative absolute change w.r.t. the previous attribute value which will trigger the event. If the attribute is a spectrum or an image then an archive event is generated if any one of the attribute value's satisfies the above criterion. If only one property is specified then it is used for the positive and negative change. If no properties are specified then the relative change is used.

3. **archive_period** - the minimum time between archive events (in milliseconds). If no property is specified then a default value of 10 seconds is used.
4.5.5.2 C++ Clients

This is the interface for clients who want to receive events. The main action of the client is to subscribe and unsubscribe to events. Once the client has subscribed to one or more events the events are received in a separate thread and the callbacks are fired in this thread.

4.5.5.2.1 Subscribing to events

The client call to subscribe to an event is named DeviceProxy::subscribe_event(). The client implements a callback method which is triggered when the event is received. Note that this callback method will be executed by a thread started by the underlying ORB. This thread is not the application main thread. On top of the user filter defined by the filters parameter, basic filtering is done based on the reason specified and the event type. For example when reading the state and the reason specified is "change" the event will be fired only when the state changes. Events consist of an attribute name and the event reason. A standard set of reasons are implemented by the system, additional device specific reasons can be implemented by device servers programmers.

\[
\text{int DeviceProxy::subscribe_event(}
\text{\quad const string &attribute,}
\text{\quad Tango::EventType event,}
\text{\quad Tango::CallBack *callback,}
\text{\quad const vector<string> &filters);}\]

4.5.5.2.2 TheCallBack class

In C++, the client has to implement a class inheriting from the Tango CallBack class and pass this to the DeviceProxy::subscribe_event() method. The CallBack class is the same class as the one proposed for the TANGO asynchronous call. This is as follows for events:

```cpp
class MyCallback : public Tango::CallBack
{
    ...
    virtual push_event(Tango::EventData *);
}
```

where EventData is defined as follows:

```cpp
class EventData
{
    DeviceProxy *device;
    string &attr_name;
    string &event;
    DeviceAttribute *attr_value;
    bool err;
    DevErrorList &errors;
}
```

4.5.5.2.3 Unsubscribing from an event

Unsubscribe a client from receiving the event specified by event_id is done by calling the DeviceProxy::unsubscribe_event() method:

```cpp
void DeviceProxy::unsubscribe_event(int event_id);
```
4.5.5.2.4 Example

Here is a typical example of what a client will need to do to register for and receive events without specifying additional filters. First, you have to define a callback method as follows:

```cpp
class DoubleEventCallBack : public Tango::CallBack
{
    void push_event(Tango::EventData*);
};

void DoubleEventCallBack::push_event(Tango::EventData *myevent)
{
    Tango::DevVarDoubleArray *double_value;
    try
    {
        cout << "DoubleEventCallBack::push_event(): called attribute "
             << myevent->attr_name
             << " event "
             << myevent->event
             << " (err-"
             << myevent->err
             << ")" << endl;
        if (!myevent->err)
        {
            myevent->attr_value >> double_value;
            cout << "double value "
                 << *((double_value)[0] << endl;
            delete double_value;
        }
        catch (...)
        {
            cout << "DoubleEventCallBack::push_event(): could not extract data !\n";
        }
    }
}
```

Then the main code must subscribe to the event:

```cpp
DoubleEventCallBack *double_callback = new DoubleEventCallBack;
vector<string> my_filters;

Tango::DeviceProxy *mydevice = new Tango::DeviceProxy("my/device/1");

int event_id;
const string attr_name("current");
event_id = mydevice->subscribe_event(attr_name,
    Tango::CHANGEEVENT,
```
CHAPTER 4. WRITING A TANGO CLIENT USING TANGO APIs

    double_callback,
    my_filters);
    cout << "event_client() id - " << event_id << endl;
    sleep(1000); // wait for events
    event_test->unsubscribe_event(event_id);

4.5.5.3 Java Clients
This is the interface for java clients who want to receive events. There are two ways to receive events using the TANGO java API:

1. Using Callback.
2. Using Java listener

Using callback, is very similar to a C++ clients. Using listener is more in the Java philosophy.

4.5.5.3.1 Using CallBack
In Java when using callback, the client has to implement a class inheriting from the Tango CallBack class and pass this to the DeviceProxy.subscribe_event() method. The CallBack class is the same class as the one proposed for the TANGO asynchronous call. This is as follows for events:

    class MyCallback extends CallBack
    {
        ...
        ...
        public void push_event(EventData evt)
        {
            ...
        }
    }

where EventData is similar to the C++ EventData class. To subscribe to an event, use the DeviceProxy.subscribe_event() method. To unsubscribe from an event, use the DeviceProxy.unsubscribe_event() method.

4.5.5.3.2 Using listeners
The Tango API defined four Java interfaces called

- ITangoChangeListener for the change event
- ITangoPeriodicListener for the periodic event
- ITangoQualityChangeListener for the quality change event
- ITangoArchiveListener for the archive event

All these interfaces defined one method respectively called change(), periodic(), qualityChange() and archive() which will be called when the event is received. The user must write a class implementing the interface for which he (she) want to receive event.
CHAPTER 4. WRITING A TANGO CLIENT USING TANGO APIs

To install or remove a listener, use the *TangoEventsAdapter* class which has methods to install/remove listeners for the four different types of listener. This TangoEventAdapter class is created from the Tango device name.

**Example** Here is a typical example of what a client will need to do to register for and receive events. First, you have to define a class implementing an interface as follows:

```java
class DoubleEventListener implements ITangoPeriodicListener
{
   public void periodic(TangoPeriodicEvent event)
   {
      DeviceAttribute attr = event.getValue();
      double[] double_value;
      try
      {
         double_value = attr.extractDoubleArray();
         System.out.println("double value " + double_value[0]);
      }
      catch (Exception e)
      {
         System.out.println("DoubleEventListener.periodic() : could not extract data!");
      }
   }
}
```

The main code looks like (suppose the device generating event is called *my/event/tester* and the attribute name is *double_event*):

```java
DoubleEventListener listener = new DoubleEventListener();
TangoEventsAdapter adapter = new TangoEventsAdapter("my/event/tester") ;
String[] filters = new String[0];
adapter.addTangoPeriodicListener(listener,"double_event",filters);
```

4.6 Group

A Tango Group provides the user with a single point of control for a collection of devices. By analogy, one could see a Tango Group as a proxy for a collection of devices. For instance, the Tango Group API supplies a *command_inout()* method to execute the same command on all the elements of a group.
A Tango Group is also a hierarchical object. In other words, it is possible to build a group of both groups and individual devices. This feature allows creating logical views of the control system - each view representing a hierarchical family of devices or a sub-system.

In this chapter, we will use the term hierarchy to refer to a group and its sub-groups. The term Group designates to the local set of devices attached to a specific Group.

### 4.6.1 Getting started with Tango group

The quickest way of getting started is to study an example...

Imagine we are vacuum engineers who need to monitor and control hundreds of gauges distributed over the 16 cells of a large-scale instrument. Each cell contains several penning and pirani gauges. It also contains one "strange" gauge. Our main requirement is to be able to control the whole set of gauges, a family of gauges located into a particular cell (e.g. all the penning gauges of the 6th cell) or a single gauge (e.g. the strange gauge of the 7th cell). Using a Tango Group, such features are quite straightforward to obtain.

Reading the description of the problem, the device hierarchy becomes obvious. Our "gauges" group will have the following structure:

```
-> gauges
 | -> cell-01
 | | -> inst-c01/vac-gauge/strange
 | | | -> penning
 | | | | | -> inst-c01/vac-gauge/penning-01
 | | | | | | -> inst-c01/vac-gauge/penning-02
 | | | | | | -> ...
 | | | | | | | -> inst-c01/vac-gauge/penning-xx
 | | | | -> pirani
 | | | | | -> inst-c01/vac-gauge/pirani-01
 | | | | | | -> ...
 | | | | | | | -> inst-c01/vac-gauge/pirani-xx
 | -> cell-02
 | | -> inst-c02/vac-gauge/strange
 | | | -> penning
 | | | | | -> inst-c02/vac-gauge/penning-01
 | | | | | | -> ...
 | | | | | | | |
 | | | | | | | | -> pirani
 | | | | | | | | | -> ...
 | | | | | | | | | | -> cell-03
 | | | | | | | | | | | -> ...
```

In the C++, such a hierarchy can be build as follows (basic version):

```c++
// step0: create the root group
Tango::Group *gauges = new Tango::Group("gauges");

// step1: create a group for the n-th cell
Tango::Group *cell = new Tango::Group("cell-01");

// step2: make the cell a sub-group of the root group
gauges->add(cell);
```
// step3: create a "penning" group
Tango::Group *gauge_family = new Tango::Group("penning");

// step4: add all penning gauges located into the cell (note the wildcard)
gauge_family->add("inst-c01/vac-gauge/penning*");

// step5: add the penning gauges to the cell
cell->add(gauge_family);

// step6: create a "pirani" group
gauge_family = new Tango::Group("pirani");

// step7: add all pirani gauges located into the cell (note the wildcard)
gauge_family->add("inst-c01/vac-gauge/pirani*");

// step8: add the pirani gauges to the cell
cell->add(gauge_family);

// step9: add the "strange" gauge to the cell
cell->add("inst-c01/vac-gauge/strange");

// repeat step 1 to 9 for the remaining cells
cell = new Tango::Group("cell-02");
...

Here is the Java version:

import fr.esrf.TangoApi.Group;

// step0: create the root group Group
gauges = new Group("gauges");

// step1: create a group for the n-th cell
Group cell = new Group("cell-01");

// step2: make the cell a sub-group of the root group
gauges.add(cell);

// step3: create a "penning" group
Group gauge_family = new Group("penning");

// step4: add all penning gauges located into the cell (note the wildcard)
gauge_family.add("inst-c01/vac-gauge/penning*");

// step5: add the penning gauges to the cell
cell.add(gauge_family);

// step6: create a "pirani" group
gauge_family = new Group("pirani");

// step7: add all pirani gauges located into the cell (note the wildcard)
gauge_family.add("inst-c01/vac-gauge/pirani");

// step 8: add the pirani gauges to the cell cell.add(gauge_family);

// step 9: add the "strange" gauge to the cell cell.add("inst-c01/vac-gauge/strange");

// repeat step 1 to 9 for the remaining cells cell = new Group("cell-02");

**Important note:** There is no particular order to create the hierarchy. However, the insertion order of the devices is conserved throughout the lifecycle of the Group and cannot be changed. That way, the Group implementation can guarantee the order in which results are returned (see below).

Keeping a reference to the root group is enough to manage the whole hierarchy (i.e. there no need to keep trace of the sub-groups or individual devices). The Group interface provides methods to retrieve a sub-group or an individual device.

Be aware that a C++ group always gets the ownership of its children and deletes them when it is itself deleted. Therefore, never try to delete a Group (respectively a DeviceProxy) returned by a call to Tango::Group::get_group() (respectively to Tango::Group::get_device()). Use the Tango::Group::remove() method instead (see the Tango Group class API documentation for details).

We can now perform any action on any element of our "gauges" group. For instance, let's ping the whole hierarchy to be sure that all devices are alive.

```cpp
// ping the whole hierarchy
if (gauges->ping() == true)
{
    std::cout << "all devices alive" << std::endl;
}
else
{
    std::cout << "at least one dead/busy/locked/... device" << std::endl;
}
```

### 4.6.2 Forward or not forward?

Since a Tango Group is a hierarchical object, any action performed on a group can be forwarded to its sub-groups. Most of the methods in the Group interface have a so-called *forward* option controlling this propagation. When set to *false*, the action is only performed on the local set of devices. Otherwise, the action is also forwarded to the sub-groups, in other words, propagated along the hierarchy. In C++, the forward option defaults to true (thanks to the C++ default argument value). There is no such mechanism in Java and the forward option must be systematically specified.

### 4.6.3 Executing a command

As a proxy for a collection of devices, the Tango Group provides an interface similar to the DeviceProxy's. For the execution of a command, the Group interface contains several implementations of the *command_inout* method. Both synchronous and asynchronous forms are supported.
4.6.3.1 Obtaining command results

Command results are returned using a Tango::GroupCmdReplyList. This is nothing but a vector containing a Tango::GroupCmdReply for each device in the group. The Tango::GroupCmdReply contains the actual data (i.e. the Tango::DeviceData). By inheritance, it may also contain any error occurred during the execution of the command (in which case the data is invalid).

We previously indicated that the Tango Group implementation guarantees that the command results are returned in the order in which its elements were attached to the group. For instance, if g1 is a group containing three devices attached in the following order:

   g1->add("my/device/01");
g1->add("my/device/03");
g1->add("my/device/02");

the results of

   Tango::GroupCmdReplyList crl = g1->command_inout("Status");

will be organized as follows:

   crl[0] contains the status of my/device/01
   crl[1] contains the status of my/device/03
   crl[2] contains the status of my/device/02

Things get more complicated if sub-groups are added "between" devices.

   g2->add("my/device/04");
g2->add("my/device/05");

g4->add("my/device/08");
g4->add("my/device/09");

g3->add("my/device/06");
g3->add(g4);
g3->add("my/device/07");

g1->add("my/device/01");
g1->add(g2);
g1->add("my/device/03");
g1->add(g3);
g1->add("my/device/02");

The result order in the Tango::GroupCmdReplyList depends on the value of the forward option. If set to true, the results will be organized as follows:

   Tango::GroupCmdReplyList crl = g1->command_inout("Status", true);

   crl[0] contains the status of my/device/01 which belongs to g1
   crl[1] contains the status of my/device/04 which belongs to g1,g2
   crl[2] contains the status of my/device/05 which belongs to g1,g2
   crl[3] contains the status of my/device/03 which belongs to g1
   crl[4] contains the status of my/device/06 which belongs to g1,g3
   crl[5] contains the status of my/device/08 which belongs to g1,g3,g4
   crl[6] contains the status of my/device/09 which belongs to g1,g3,g4
   crl[7] contains the status of my/device/07 which belongs to g1,g3
   crl[8] contains the status of my/device/02 which belongs to g1

If the forward option is set to false, the results are:

   Tango::GroupCmdReplyList crl = g1->command_inout("Status", false);
4.6.3.2 Case 1: a command, no argument

As an example, we execute the Status command on the whole hierarchy synchronously.

```cpp
Tango::GroupCmdReplyList cr1 = gauges->command_inout("Status");
```

As a first step in the results processing, it could be interesting to check value returned by the has_failed() method of the GroupCmdReplyList. If it is set to true, it means that at least one error occurred during the execution of the command (i.e. at least one device gave error).

```cpp
if (cr1.has_failed())
{
    cout << "at least one error occurred" << endl;
}
else
{
    cout << "no error" << endl;
}
```

In Java, we should write:

```java
import fr.esrf.TangoApi.Group;
GroupCmdReplyList cr1 = gauges.command_inout("Status",true);
if (cr1.has_failed())
{
    System.out.println("at least one error occurred");
}
else
{
    System.out.println("no error");
}
```

Now, we have to process each "individual response" in the list.

4.6.3.3 A few words on error handling and data extraction

Depending on the application and/or the developer's programming habits, each individual error can be handled by the C++ (or Java) exception mechanism or using the dedicated has_failed() method. The GroupReply class - which is the mother class of both GroupCmdReply and GroupAttrReply - contains a static method to enable (or disable) exceptions called enable_exception(). By default,
exceptions are disabled (in both Java and C++). The following example is proposed with both exceptions enable and disable.

In C++, data can be extracted directly from an individual reply. The GroupCmdReply interface contains a template operator \( \gg \) allowing the extraction of any supported Tango type (in fact the actual data extraction is delegated to DeviceData\( \gg \) operator \( \gg \)). One dedicated extract method is also provided in order to extract DevVarLongStringArray and DevVarDoubleStringArray types to std::vectors.

Error and data handling C++ example:

```cpp
//synch. group command example with exception enabled
//-------------------------------
// enable exceptions and save current mode
bool last_mode = GroupReply::enable_exception(true);
// process each response in the list ...
for (int r = 0; r < crl.size(); r++)
{
    // enter a try/catch block
    try
    {
        // try to extract the data from the r-th reply
        // suppose data contains a double
        double ans;
        crl[r] >> ans;
        cout << crl[r].dev_name()
             << "::"
             << crl[r].obj_name()
             << " returned "
             << ans
             << endl;
    }
    catch (const DevFailed& df)
    {
        // DevFailed caught while trying to extract the data from reply
        for (int err = 0; err < df.errors.length(); err++)
        {
            cout << "error: " << df.errors[err].desc.in() << endl;
        }
        // alternatively, one can use crl[r].get_err_stack() see below
    }
    catch (...)
    {
        cout << "unknown exception caught";
    }
}
// restore last exception mode (if needed)
GroupReply::enable_exception(last_mode);
// Clear the response list (if reused later in the code)
crl.reset();
//-------------------------------
// synch. group command example with exception disabled
```
```cpp
// disable exceptions and save current mode
bool last_mode = GroupReply::enable_exception(false);

// process each response in the list ...
for (int r = 0; r < crl.size(); r++)
{
    // did the r-th device give error?
    if (crl[r].has_failed() == true)
    {
        // printout error description
        cout << "an error occurred while executing "
             << crl[r].obj_name()
             << " on "
             << crl[r].dev_name() << endl;
        // dump error stack
        const DevErrorList& el = crl[r].get_err_stack();
        for (int err = 0; err < el.size(); err++)
        {
            cout << el[err].desc.in();
        }
    }
    else
    {
        // no error (suppose data contains a double)
        double ans;
        bool result = crl[r] >> ans;
        if (result == false)
        {
            cout << "could not extract double from "
                 << crl[r].dev_name()
                 << " reply"
                 << endl;
        }
        else
        {
            cout << crl[r].dev_name()
                 << ":="
                 << crl[r].obj_name()
                 << " returned "
                 << ans
                 << endl;
        }
    }
}
// restore last exception mode (if needed)
GroupReply::enable_exception(last_mode);
// Clear the response list (if reused later in the code)
crl.reset();
```

Error and data handling Java example:
/*------------------------------------------------*/
/* synch. group command example with exception enabled */
/*------------------------------------------------*/

// enable exceptions and save current mode
boolean last_mode = GroupReply.enable_exception(true);

// process each response in the list ...
Iterator it = cr1.iterator();
// try to extract the data from the each reply
// suppose data contains a double
double ans;
while (it.hasNext()) {
    // cast from Object to GroupCmdreply
    GroupCmdreply cr = (GroupCmdreply)it.next();
    // enter a try/catch block
    try {
        // extract value from data (may throw DevFailed)
        ans = get_data().extractDouble();
        // verbose
        System.out.println(cr.dev_name() + "::
                + cr.obj_name() + " returned "
                + ans);
    }
    catch (DevFailed d) {
        // DevFailed caught while trying to extract the data from reply
        for (int err = 0; err < d.errors.length; err++) {
            System.out.println("error: " + d.errors[err].desc);
        }
        // alternatively, one can use cr.get_err_stack() see below
    }
    catch (Exception e) {
        System.out.println("unknown exception caught");
    }
}
// restore last exception mode (if needed)
GroupReply.enable_exception(last_mode);

/*------------------------------------------------*/
/* synch. group command example with exception disabled */
/*------------------------------------------------*/

// disable exceptions and save current mode
boolean last_mode = GroupReply.enable_exception(false);
// process each response in the list ...
Iterator it = cr1.iterator();
// try to extract the data from the each reply
while (it.hasNext()) {

CHAPTER 4. WRITING A TANGO CLIENT USING TANGO APIs

// cast from Object to GroupCmdreply  
GroupCmdreply cr - (GroupCmdreply) it.next();
// did the device give error?
if (cr.has_failed() -- true)
{

// printout error description
    System.out.println("an error occurred while executing 
        + cr.obj_name()
        + " on "
        + cr.dev_name());
// dump error stack
    DevError[] de = cr.get_err_stack();
    for (int err - 0; err < de.length; err++)
    {
        System.out.println("error: " + de[err].desc);
    }
} else
{
// no error (suppose data contains a double)
    double ans - cr.get_data().extractDouble();
// verbose
    System.out.println(cr.dev_name()
        + ":"
        + cr.obj_name()
        + " returned "
        + ans);
}
// restore last exception mode (if needed)
GroupReply.enable_exception(last_mode);

Now execute the same command asynchronously. C++ example:

//-------------------------------
// asynch. group command example (C++ example)
//-------------------------------
long request_id - gauges->command_inout_asynch("Status");
// do some work
do_some_work();

// get results
    crl - gauges->command_inout_reply(request_id);
// process responses as previously describe in the synch. implementation
for (int r - 0; r < crl.size(); r++)
{
    // data processing and error handling goes here
    // copy/paste code from previous example
    ...
}
```cpp
// clear the response list (if reused later in the code)
crl.reset();
```

The same asynchronous example in Java:

```java
// -------------------------------
// asynch. group command example (Java example)
// -------------------------------
int request_id = gauges.command_inout_asynch("Status",false,true);
// do some work
do_some_work();

// get results
crl = gauges.command_inout_reply(request_id);
// process responses as previously describe in the synch. implementation
Iterator it = crl.iterator();
// try to extract the data from the each reply
while (it.hasNext())
{
    // data processing and error handling goes here
    // copy/paste code from previous example
    ...
}
```

### 4.6.3.4 Case 2: a command, one argument

Here, we give an example in which the same input argument is applied to all devices in the group (or its sub-groups).

In C++:

```cpp
// the argument value
double d = 0.1;
// insert it into the TANGO generic container for command: DeviceData
Tango::DeviceData dd;
dd << d;
// execute the command: Dev_Void SetDummyFactor (Dev_Double)
Tango::GroupCmdReplyList crl = gauges->command_inout("SetDummyFactor", dd);
```

In Java:

```java
// the argument value
double d = 0.1;
// insert it into the TANGO generic container for command: DeviceData
```
DeviceData dd = new DeviceData();
    dd.insert(d);
    // execute the command: Dev_Void SetDummyFactor (Dev_Double)
    GroupCmdReplyList crl = gauges.command_inout("SetDummyFactor", dd, false, true);

Since the SetDummyFactor command does not return any value, the individual replies (i.e. the
GroupCmdReply) do not contain any data. However, we have to check their has_failed() method
returned value to be sure that the command completed successfully on each device (acknowledge-
ment). Note that in such a case, exceptions are useless since we never try to extract data from
the replies.

In C++ we should have something like:

    // no need to process the results if no error occurred (Dev_Void command)
    if (crl.has_failed())
    {
        // at least one error occurred
        for (int r = 0; r < crl.size(); r++)
        {
            // handle errors here (see previous C++ examples)
        }
    }
    // clear the response list (if reused later in the code)
    crl.reset();

While in Java

    // no need to process the results if no error occurred (Dev_Void command)
    if (crl.has_failed())
    {
        // at least one error occurred
        for (int r = 0; r < crl.length; r++)
        {
            // handle errors here (see previous Java examples)
        }
    }

See case 1 for an example of asynchronous command.

4.6.3.5 Case 3: a command, several arguments

Here, we give an example in which a specific input argument is applied to each device in the
hierarchy. In order to use this form of command_inout, the user must have an "a priori" and
"perfect" knowledge of the devices order in the hierarchy. In such a case, command arguments
are passed in an "array" (with one entry for each device in the hierarchy).
CHAPTER 4. WRITING A TANGO CLIENT USING TANGO API S

The C++ implementation provides a template method which accepts a std::vector of "C++ type for command argument". This allows passing any kind of data using a single method.

Since templates are not (already) supported in Java, the implementation is somewhat different and an array of DeviceData is used to pass the specific arguments.

In both cases (C++ and Java), the size of this vector must equal the number of device in the hierarchy (respectively the number of device in the group) if the forward option is set to true (respectively set to false). Otherwise, an exception is thrown.

The first item in the vector is applied to the first device in the hierarchy, the second to the second device in the hierarchy, and so on... That's why the user must have a "perfect" knowledge of the devices order in the hierarchy.

Assuming that gauges are ordered by name, the SetDummyFactor command can be executed on group "cell-01" (and its sub-groups) as follows:

Remember, "cell-01" has the following internal structure:

```
- > gauges
  | - > cell-01
  |   | - > inst-c01/vac-gauge/strange
  |   | - > penning
  |   |   | - > inst-c01/vac-gauge/penning-01
  |   |   | - > inst-c01/vac-gauge/penning-02
  |   |   |   | - > ...
  |   |   | - > inst-c01/vac-gauge/penning-xx
  |   | - > pirani
  |   |   | - > inst-c01/vac-gauge/pirani-01
  |   |   |   | - > ...
  |   |   | - > inst-c01/vac-gauge/pirani-xx
```

Passing a specific argument to each device in C++:

```cpp

// get a reference to the target group
Tango::Group *g = gauges->get_group("cell-01");
// get number of device in the hierarchy (starting at cell-01)
long n_dev = g->get_size(true);
// Build argin list
std::vector<double> args(n_dev);
// argument for inst-c01/vac-gauge/strange
args[0] = 0.0;
// argument for inst-c01/vac-gauge/penning-01
args[1] = 0.1;
// argument for inst-c01/vac-gauge/penning-02
args[2] = 0.2;
// argument for remaining devices in cell-01.penning
;
// argument for devices in cell-01.pirani
;
// the reply list
Tango::GroupCmdReplyList crl;
// enter a try/catch block (see below)
try {
// execute the command
crl = g->command_inout("SetDummyFactor", args, true);
    if (crl.has_failed())
```

{  
   // error handling goes here (see case i)
}
catch (const DevFailed& df)
{
   // see below
}
crl.reset();

If we want to execute the command locally on "cell-01" (i.e. not on its sub-groups), we should write the following C++ code:

```cpp
// get a reference to the target group
Tango::Group *g = gauges->get_group("cell-01");
// get number of device in the group (starting at cell-01)
long n_dev = g->get_size(false);
// Build argin list
std::vector<double> args(n_dev);
// args for inst-c01/vac-gauge/penning-01
args[0] = 0.1;
// args for inst-c01/vac-gauge/penning-02
args[1] = 0.2;
// args for remaining devices in cell-01.penning
...
// the reply list
Tango::GroupCmdReplyList crl;
// enter a try/catch block (see below)
try {
   // execute the command
   crl = g->command_inout("SetDummyFactor", args, false);
   if (crl.has_failed())
   {
      // error handling goes here (see case i)
   }
}
catch (const DevFailed& df)
{
   // see below
}
crl.reset();
```

Passing a specific argument to each device in Java:

```java
// get a reference to the target group
Group g = gauges.get_group("cell-01");
```
CHAPTER 4. WRITING A TANGO CLIENT USING TANGO APIs

// get pre-build arguments list for the whole hierarchy (starting@cell-01)  
DeviceData[] args = g.get_command_specific_argument_list(true);  
// argument for inst-c01/vac-gauge/strange  
args[0].insert(0.0);  
// argument for inst-c01/vac-gauge/penning-01  
args[1].insert(0.1);  
// argument for inst-c01/vac-gauge/penning-02  
args[2].insert(0.2);  
// argument for remaining devices in cell-01.penning  
...  
// argument for devices in cell-01.pirani  
...  
// the reply list GroupCmdReplyList  
crl = null;  
// enter a try/catch block (see below)  
try  
{  
  // execute the command  
  crl = g.command_inout("SetDummyFactor", args, false, true);  
  if (crl.has_failed())  
  {  
    // error handling goes here (see case 1)  
  }  
}  
catch (DevFailed d)  
{  
  // see below  
}

Note: if we want to execute the command locally on "cell-01" (i.e. not on its sub-groups), we  
should write the following code:

// get a reference to the target group  
Group g = gauges.get_group("cell-01");  
// get pre-build arguments list for the group (starting@cell-01)  
DeviceData[] args = g.get_command_specific_argument_list(false);  
// args for inst-c01/vac-gauge/penning-01  
args[0].insert(0.1);  
// args for inst-c01/vac-gauge/penning-02  
args[1].insert(0.2);  
// args for remaining devices in cell-01.penning  
...  
// the reply list  
GroupCmdReplyList crl;  
// enter a try/catch block (see below)  
try  
{  
  // execute the command  
  crl = g.command_inout("SetDummyFactor", args, false, false);  
  if (crl.has_failed())  
  {  

This form of `command_inout` (the one that accepts an array of value as its input argument), may throw an exception before executing the command if the number of elements in the input array does not match the number of individual devices in the group or in the hierarchy (depending on the forward option).

Java developers should use the `Group.get_command_specific_argument_list` helper method (see previous example). It guarantees than the "returned array" has the right number of elements. This array may be kept and reused as far as the group size is not changed (i.e. no add or remove of elements).

An asynchronous version of this method is also available. See case 1 for an example of asynchronous command.

### 4.6.4 Reading an attribute

In order to read an attribute, the Group interface contains several implementations of the `read_attribute()` method. Both synchronous and asynchronous forms are supported. However, reading more than one attribute at a time is not supported.

#### 4.6.4.1 Obtaining attribute values

Attribute values are returned using a `GroupAttrReplyList`. This is nothing but an array containing a `GroupAttrReply` for each device in the group. The `GroupAttrReply` contains the actual data (i.e. the `DeviceAttribute`). By inheritance, it may also contain any error occurred during the execution of the command (in which case the data is invalid).

Here again, the Tango Group implementation guarantees that the attribute values are returned in the order in which its elements were attached to the group. See Obtaining command results for details.

The `GroupAttrReply` contains some public methods allowing the identification of both the device (`GroupAttrReply::dev_name`) and the attribute (`GroupAttrReply::obj_name`). It means that, depending of your application, you can associate a response with its source using its position in the response list or using the `Tango::GroupAttrReply::dev_name` member.

#### 4.6.4.2 A few words on error handling and data extraction

Here again, depending of the application and/or the developer’s programming habits, each individual error can be handle by the C++ exception mechanism or using the dedicated `has_failed()` method. The `GroupReply` class - which is the mother class of both `GroupCmdReply` and `GroupAttrReply` - contains a static method to enable (or disable) exceptions called `enable_exception()`. By default, exceptions are disabled (in both Java and C++). The following example is proposed with both exceptions enable and disable.

In C++, data can be extracted directly from an individual reply. The `GroupAttrReply` interface contains a template operator `>>` allowing the extraction of any supported Tango type (in fact the actual data extraction is delegated to `DeviceAttribute::operator >>`).

Reading an attribute is very similar to executing a command.

Reading an attribute in C++:
// --synch. read "vacuum" attribute on each device in the hierarchy
// - with exceptions enabled - C++ example
// -- enable exceptions and save current mode
bool last_mode = GroupReply::enable_exception(true);
// - read attribute
Tango::GroupAttrReplyList arl = gauges->read_attribute("vacuum");
// - for each response in the list ...
for (int r = 0; r < arl.size(); r++)
{
  // - enter a try/catch block
  try
  {
    // - try to extract the data from the r-th reply
    // - suppose data contains a double
    double ans;
    arl[r] >> ans;
    cout << arl[r].dev_name()
    << ":"
    << arl[r].obj_name()
    << " value is "
    << ans << endl;
  }
  catch (const DevFailed& df)
  {
    // - DevFailed caught while trying to extract the data from reply
    for (int err = 0; err < df.errors.length(); err++)
    {
      cout << "error: " << df.errors[err].desc.in() << endl;
    }
    // - alternatively, one can use arl[r].get_err_stack() see below
    catch (...)
    {
      cout << "unknown exception caught";
    }
  }
  // - restore last exception mode (if needed)
  GroupReply::enable_exception(last_mode);
  // - clear the reply list (if reused later in the code)
  arl.reset();

Reading an attribute in Java:

// --synch. read "vacuum" attribute on each device in the hierarchy
// - with exceptions enabled - Java example
// -- enable exceptions and save current mode
boolean last_mode = GroupReply.enable_exception(true);
// - read attribute
Tango.GroupAttrReplyList arl = gauges.read_attribute("vacuum");
// - for each response in the list ...
for (int r = 0; r < arl.size(); r++)
{
  // - enter a try/catch block
  try
  {
    // - try to extract the data from the r-th reply
    // - suppose data contains a double
    double ans;
    arl[r] >> ans;
    System.out.println(arl[r].dev_name() + " value is " + ans + "");
  }
  catch (Exception e)
  {
    // - DevFailed caught while trying to extract the data from reply
    for (int err = 0; err < e.errors.length(); err++)
    {
      System.out.println("error: " + e.errors[err].desc.in());
    }
    // - alternatively, one can use arl[r].get_err_stack() see below
    catch (...)
    {
      System.out.println("unknown exception caught");
    }
  }
  // - restore last exception mode (if needed)
  GroupReply.enable_exception(last_mode);
  // - clear the reply list (if reused later in the code)
  arl.reset();
CHAPTER 4. WRITING A TANGO CLIENT USING TANGO APIs

// enable exceptions and save current mode
boolean last_mode = GroupReply.enable_exception(true);

// read attribute
GroupAttrReplyList arl = gauges.read_attribute("vacuum",true);

// try to extract the data from each reply
// suppose data contains a double
double ans;
while (arl.hasNext())
{
    // cast from Object to GroupAttrReply
    GroupAttrReply ar = (GroupAttrReply)arl.next();
    // enter a try/catch block
    try
    {
        // extract value from data (may throw DevFailed)
        ans = ar.get_data().extractDouble();
        // verbose
        System.out.println(cr.dev_name() + ":" + cr.obj_name() + " returned " + ans);
    }
    catch (DevFailed d)
    {
        // DevFailed caught while trying to extract the data from reply
        for (int err = 0; err < d.errors.length; err++)
        {
            System.out.println("error: " + d.errors[err].desc);
        }
        // alternatively, one can use cr.get_err_stack() see below
    }
    catch (Exception e)
    {
        System.out.println("unknown exception caught");
    }
}
// restore last exception mode (if needed)
GroupReply.enable_exception(last_mode);

In C++, an asynchronous version of the previous example could be:

// read the attribute asynchronously
long request_id = gauges->read_attribute_asynch("vacuum");
// do some work
do_ssome_work();

// get results
Tango::GroupAttrReplyList arl = gauges->read_attribute_reply(request_id);
// process replies as previously described in the synch. implementation
for (int r = 0; r < arl.size(); r++)
{
    // data processing and/or error handling goes here
    ...
}
    // clear the reply list (if reused later in the code)
arl.reset();

The same asynchronous example in Java:

    // read the attribute asynchronously
    int request_id = gauges.read_attribute_asynch("vacuum",true);
    // do some work
    do_some_work();

    // get results
    GroupAttrReplyList arl = gauges.read_attribute_reply(request_id);
    Iterator it = arl.iterator();
    // try to extract the data from the each reply
    while (it.hasNext())
    {
        // data processing and error handling goes here
        // copy/paste code from previous example
        . . .
    }

4.6.5 Writing an attribute

The Group interface contains several implementations of the write_attribute() method. Both synchronous and asynchronous forms are supported. However, writing more than one attribute at a time is not supported.

4.6.5.1 Obtaining acknowledgement

Acknowledgements are returned using a GroupReplyList. This is nothing but an array containing a GroupReply for each device in the group. The GroupReply may contain any error occurred during the execution of the command. The return value of the has_failed() method indicates whether an error occurred or not. If this flag is set to true, the GroupReply::get_err_stack() method gives error details.

Here again, the Tango Group implementation guarantees that the attribute values are returned in the order in which its elements were attached to the group. See Obtaining command results for details.

The GroupReply contains some public members allowing the identification of both the device (GroupReply:dev_name) and the attribute (GroupReply::obj_name). It means that, depending of your application, you can associate a response with its source using its position in the response list or using the GroupReply:dev_name member.
4.6.5.2 Case 1: one value for all devices

Here, we give an example in which the same attribute value is written on all devices in the group (or its sub-groups). Exceptions are supposed to be disabled.

Writing an attribute in C++:

```cpp
// --------------------------------------------------------------
//-- synch. write "dummy" attribute on each device in the hierarchy
//-- --------------------------------------------------------------
//-- assume each device support a "dummy" writable attribute
//-- insert the value to be written into a generic container
Tango::DeviceAttribute value(std::string("dummy"), 3.14159);
//-- write the attribute
Tango::GroupReplyList rl = gauges->write_attribute(value);
//-- any error?
if (rl.has_failed() == false)
{
  cout << "no error" << endl;
}
else
{
  cout << "at least one error occurred" << endl;
  // for each response in the list ...
  for (int r = 0; r < rl.size(); r++)
  {
    // did the r-th device give error?
    if (rl[r].has_failed() == true)
    {
      // printout error description
      cout << "an error occurred while reading "
          << rl[r].obj_name()
          << " on "
          << rl[r].dev_name()
          << endl;
      // dump error stack
      const DevErrorList& el = rl[r].get_err_stack();
      for (int err = 0; err < el.size(); err++)
      {
        cout << el[err].desc.in();
      }
    }
  }
  // clear the reply list (if reused later in the code)
  rl.reset();
}
```

Writing an attribute in Java:

```java
// --------------------------------------------------------------
//-- synch. write "dummy" attribute on each device in the hierarchy
//-- --------------------------------------------------------------
```
Here is a C++ asynchronous version:

```cpp
// insert the value to be written into a generic container
Tango::DeviceAttribute value(std::string("dummy"), 3.14159);
// write the attribute asynchronously
long request_id = gauges.write_attribute_asynch(value);
// do some work
do_some_work();

// get results
Tango::GroupReplyList rl = gauges->write_attribute_reply(request_id);
// process replies as previously describe in the synch. implementation ...
```
4.6.5.3 Case 2: a specific value per device

Here, we give an example in which a specific attribute value is applied to each device in the hierarchy. In order to use this form of write_attribute(), the user must have an "a priori" and "perfect" knowledge of the devices order in the hierarchy.

The C++ implementation provides a template method which accepts a std::vector of "C++ type for command argument". This allows passing any kind of data using a single method.

Since templates are not (already) supported in Java, the implementation is somewhat different and an array of DeviceAttribute is used to pass the specific arguments.

In both cases (C++ and Java), the size of this vector must equal the number of device in the hierarchy (respectively the number of device in the group) if the forward option is set to true (respectively set to false). Otherwise, an exception is thrown.

The first item in the vector is applied to the first device in the group, the second to the second device in the group, and so on... That's why the user must have a "perfect" knowledge of the devices order in the group.

Assuming that gauges are ordered by name, the dummy attribute can be written as follows on group "cell-01" (and its sub-groups) as follows:

Remember, "cell-01" has the following internal structure:

```bash
devices
  |--> gauges
  |     |--> cell-01
  |     |     |--> inst-c01/vac-gauge/strange
  |     |     |--> penning
  |     |     |     |--> inst-c01/vac-gauge/penning-01
  |     |     |     |--> inst-c01/vac-gauge/penning-02
  |     |     |     |--> ...
  |     |     |--> inst-c01/vac-gauge/penning-xx
  |     |--> pirani
  |     |     |--> inst-c01/vac-gauge/pirani-01
  |     |     |--> ...
  |     |     |--> inst-c01/vac-gauge/pirani-xx
```

C++ version:
CHAPTER 4. WRITING A TANGO CLIENT USING TANGO APIs

// get a reference to the target group
Tango::Group *g = gauges->get_group("cell-01");
// get number of device in the hierarchy (starting at cell-01)
long n_dev = g->get_size(true);
// Build value list
std::vector<double> values(n_dev);
// value for inst-c01/vac-gauge/strange
values[0] = 3.14159;
// value for inst-c01/vac-gauge/penning-01
values[1] = 2 * 3.14159;
// value for inst-c01/vac-gauge/penning-02
values[2] = 3 * 3.14159;
// value for remaining devices in cell-01.penning
...  
// value for devices in cell-01.pirani
...
// the reply list
Tango::GroupReplyList rl;
// enter a try/catch block (see below)
try
{
  // write the "dummy" attribute
  rl = g->write_attribute("dummy", values, true);
  if (rl.has_failed())
  {
    // error handling (see previous cases)
  }
}
catch (const DevFailed& df)
{
  // see below
}
rl.reset();

Here is a Java version:

// get a reference to the target group
Group g = gauges.get_group("cell-01");
// get pre-build arguments list for the whole hierarchy (starting@cell-01)
DeviceAttribute[] values = g.get_attribute_specific_value_list(true);
// value for inst-c01/vac-gauge/strange
values[0] = 3.14159;
// value for inst-c01/vac-gauge/penning-01
values[1] = 2 * 3.14159;
// value for inst-c01/vac-gauge/penning-02
values[2] = 3 * 3.14159;
// value for remaining devices in cell-01.penning
...
// value for devices in cell-01.pirani
...
// the reply list
GroupReplyList rl;
try
{
    // write the "dummy" attribute
    rl = g.write_attribute("dummy", values, true);
    if (rl.has_failed())
    {
        // error handling (see previous cases)
    }
}
catch (DevFailed d)
{
    // see below
}

Note: if we want to execute the command locally on "cell-01" (i.e. not on its sub-groups), we should write the following code (example is only proposed for C++ - Java port is straightforward):

    // get a reference to the target group
    Tango::Group *g = gauges->get_group("cell-01");
    // get number of device in the group
    long n_dev = g->get_size(false);
    // Build value list
    std::vector<double> values(n_dev);
    // value for inst-c01/vac-gauge/penning-01
    values[0] = 2 * 3.14159;
    // value for inst-c01/vac-gauge/penning-02
    values[1] = 3 * 3.14159;
    // value for remaining devices in cell-01.penning
    ...
    // the reply list
    Tango::GroupReplyList rl;
    // enter a try/catch block (see below)
    try
    {
        // write the "dummy" attribute
        rl = g->write_attribute("dummy", values, false);
        if (rl.has_failed())
        {
            // error handling (see previous cases)
        }
    }
catch (const DevFailed& df)
{
    // see below
}
rl.reset();

This form of write_attribute() (the one that accepts an array of value as its input argument), may throw an exception before executing the command if the number of elements in the input
array does not match the number of individual devices in the group or in the hierarchy (depending on the forward option).

Java developers should use the `Group.get_attribute_specific_value_list` helper method (see previous example). It guarantees that the "returned array" has the right number of elements. This array may be kept and reused as far as the group size is not changed (i.e. no add or remove of elements).

An asynchronous version of this method is also available.

### 4.7 Reconnection and exception

The Tango API automatically manages re-connection between client and server in case of communication error during a network access between a client and a server. By default, when a communication error occurs, an exception is returned to the caller and the connection is internally marked as bad. On the next try to contact the device, the API will try to re-build the network connection. With the `set_transparency_reconnection()` method of the `DeviceProxy` class, it is even possible not to have any exception thrown in case of communication error. The API will try to re-build the network connection as soon as it is detected as bad. See 6.17 for more details on this subject.

### 4.8 Compiling and linking a Tango client

Compiling and linking a Tango client is similar to compiling and linking a Tango device server. Please, refer to chapter "Compiling, Linking and executing a Tango device server process" (8.6) to get all the details.
Chapter 5

TANGO Java API

This chapter documents the Java API for the TANGO database and device servers.
5.1 Introduction

5.1.1 Description
This chapter documents the high level interface for Java.

Remarks:
This java api is based on Jaccor ORB implementation. The Jaccor and Tango classes are both available in TangORB.jar file.

5.1.2 Basic Philosophy
The basic philosophy is to have high level classes for the database, properties, device, group and database object info. Classes also exist for sending and receiving database or device values.
CHAPTER 5. TANGO JAVA API

All classes and data types are defined in `fr.esrf.TangoApi` package. Group related classes are in a package called `fr.esrf.TangoApi.Group`. Event related classes are in a package called `fr.esrf.TangoApi.events`

5.1.3 Classes
5.1.3.1 Data object classes
DeviceData: Object used to send and receive data on device.
DbDatum: Object used to put or get properties on database.
DbDevInfo: Object used to read device information on database.
DbDevImportInfo: Object used to read imported device information on database.
DbDevExportInfo: Object used to read exported device information on database.

5.1.3.2 Asynchronous callback related classes
CallBack: Object called at asynchronous call reply
CmdDoneEvent: Object to pass asynchronous command reply data to a CallBack object.
ReadAttrEvent: Object to pass asynchronous read_attribute reply data to a CallBack object.
AttrWrittenEvent: Object to pass asynchronous write_attribute reply data to a CallBack object.

5.1.3.3 Devices and Database access classes
DeviceProxy: Device access (aggregates DbDevice class).
Group: Multiple device access class
Database: Direct access to TANGO database.
DbClass: Class properties access to TANGO database.
DbServer: Server properties access to TANGO database.
DbDevice: Device properties access to TANGO database.

5.1.4 Reporting errors
For the device and database classes, most methods throw a DevFailed exception in case of error. See Writing a TANGO Device Server chapter Reporting Errors (§2.4), except those which specified.

In opposite, for the data object classes, only the specified method throw DevFailed exception in case of error.

The reason field could be set to:

- `TangoApi.TANGO_HOST_NOT_SET` : The TANGO_HOST environment variable has not been set or has been set with a syntax error.
- `TangoApi.DATABASE_CONNECTION_FAILED` : The database server cannot be connected (bad TANGO_HOST or database server stopped).
- `TangoApi.CANNOT_IMPORT_DEVICE` : The device is exported but cannot be connected.
- `TangoApi.DEVICE_NOT_EXPORTED` : The device has not be exported.
CHAPTER 5. TANGO JAVA API

5.1.5 Compiling a Java client

5.1.5.1 Supported java release
Tango client written using Java language needs release 1.4.0 (or above) of the Java environment.

5.1.5.2 Setting CLASSPATH and other environment variables
To correctly compile a Java Tango client, the CLASSPATH environment variable must be set to:

- The jar file with all the Tango, TangoDs, TangoApi and Jacorb package classes. This file is named TangORB.jar.
- The jar file with all the JDK classes (not always necessary, could be implicit)
- Your own package directory

For UNIX like operating system, setting environment variable is done with the export or setenv command depending on the shell used. For Windows NT, setting environment variable is possible with the “Environment” tab of the “System” application in the control panel.

The client/server timeout as been fixed by default to 3000 milliseconds but it can be set to another value a startup using TANGO_TIMEOUT environment variable.

eg: java -DTango_HOST=hal:20000 -DTango_TIMEOUT=5000 mypackage.MyClient

Will start MyClient class using the database server running on the host named hal on port 20000 with a command timeout of 5 seconds.

5.2 Data object classes

5.2.1 DeviceData class
This class manage data object for Tango device access.

5.2.1.1 Public methods

5.2.1.1.1 public DeviceData()
Constructor for DeviceData Object.
This method needs a database connection, that means that a DevFailed exception is thrown if the connection failed.

5.2.1.1.2 public void insert(<Tango type> argin)
Insert method for argin, where argin can be one of the Tango type (boolean, short, String[]...). This value will be used as argin parameter for the command _inout0 method.

5.2.1.1.3 insertion for unsigned.
- public void insert_us(short argin) : Insert method for argin short as unsigned short.
- public void insert_us(int argin) : Insert method for argin int as unsigned short.
- public void insert_us(short[] argin) : Insert method for argin short array as unsigned short array.
- public void insert_us(int[] argin) : Insert method for argin int array as unsigned short array.
• public void insert_ul(int argin) : Insert method for argin int as unsigned int.
• public void insert_ul(long argin) : Insert method for argin long as unsigned int.
• public void insert_ul(int[][] argin) : Insert method for argin int array as unsigned int array.
• public void insert_ul(long[][] argin) : Insert method for argin long array as unsigned int array.

5.2.1.4 public <TangoType> extract<Tango type>()
Extract the argout value of the command _inout() method.
i.e:
public short extractShort(): extract method for a short.
public int extractUShort(): extract method for an unsigned short.
public double extractDouble(): extract method for a double.
public String extractString(): extract method for a String.
public String[] extractStringArray(): extract method for a String array.
public float[] extractFloatArray(): extract method for a float array.
public long[] extractULongArray(): extract method for a float array.

WARNING: Due to the IDL mapping, the Tango_DevLong is an int for java! That means that the extractLong method returns an int (and not a long).

5.2.2 Example

    // Send a write command to the device
    DeviceData argin = new DeviceData();
    argin.insert("Hello World!");
    dev.command_inout("DevWriteMessage", argin);

    // Send a read command to the device
    DeviceData argout = dev.command_inout("DevReadMessage");
    String received = argout.extractString();
    System.out.println(received);

5.2.2 DeviceDataHistory
This class manage device data for history command or attribute call.
It extends the DeviceData class.

5.2.2.1 Public fields
• public int source : Contains the data source (DeviceDataHistory.COMMAND or DeviceDataHistory.ATTRIBUTE).
• public String name : The Command/Attribute name.
• public boolean failed : true if command/attribute hardware failed.
• public DevError[] errors : Error list if any in during hardware command or attribute.
5.2.2.2 Public methods

5.2.2.2.1 public DeviceDataHistory(String cmdname, DevCmdHistory cmd_histo)
Constructor from a DevCmdHistory object.
- parameter cmdname : The Command/Attribute name.
- parameter cmd_histo : The IDL data object.

5.2.2.2.2 public DeviceDataHistory(DevAttrHistory att_histo)
Constructor from an AttributeValue object.
- parameter att_histo : The IDL data object.

5.2.2.2.3 public TimeVal getTimeVal()
Return attribute time value.

5.2.2.2.4 public long getTimeValSec()
Return attribute time value in seconds since EPOCH.

5.2.2.2.5 public long getTime()
Return time in milliseconds since EPOCH to build a Date class.

5.2.2.2.6 public AttributeValue getAttributeValueObject()
Return AttributeValue if from attribute.

5.2.2.2.7 public AttrQuality getAttrQuality()
Return AttrQuality if from attribute.

5.2.2.2.8 public int getDimX()
Return attribute dim_x if from attribute.

5.2.2.2.9 public int getDimY()
Return attribute dim_y if from attribute.

5.2.3 CommandInfo
This class is an interface with the DevCmdInfo IDL object (see Reference Part for IDL).

5.2.3.1 Public fields
- public String cmd_name : Command name
- public DispLevel level : Display level DispLevel.OPERATORb or DispLevel.EXPERT
- public int in_type : Input argument type
- public int out_type : Output argument type
- public String in_type_desc : Input argument description
• String out_type_desc : Output argument description public

5.2.4 AttributeInfo
This class is an interface with the AttributeConfig IDL object (see Reference Part for IDL).

5.2.4.1 Public fields
• public String name : Attribute name.
• public AttrWriteType writable : Attribute writable state.
• public AttrDataFormat data_format : Attribute data format.
• public int data_type : Attribute data type.
• public int max_dim_x : Attribute maximum size for X dimension.
• public int max_dim_y : Attribute maximum size for Y dimension.
• public String description : Attribute description.
• public String label : Attribute label.
• public String unit : Attribute unit.
• public String standard_unit : Attribute standard unit.
• public String display_unit : Attribute display unit.
• public String format : Attribute display format.
• public String min_value : Attribute minimum value.
• public String max_value : Attribute maximum value.
• public String min_alarm : Attribute minimum value before alarm.
• public String max_alarm : Attribute maximum value before alarm.
• public String writable_attr_name : Attribute writable associated.
• public DispLevel level : Attribute display level. DispLevel.OPERATOR or DispLevel.EXPERT

5.2.5 AttributeInfoEx
This class extends AttributeInfo class with added data members.

5.2.5.1 Public fields
• public AttributeAlarmInfo alarms;
• public AttributeEventInfo events;
• public String[] extensions;
• public String[] sys_extensions;
5.2.6 AttributeAlarmInfo
This class is the same class as AttributeAlarm, but created for C++ compatibility.

5.2.6.1 Public fields
- public String min_alarm ;
- public String max_alarm;
- public String min_warning;
- public String max_warning;
- public String delta_t;
- public String delta_val;
- public String[] extensions;

5.2.7 AttributeEventInfo
This class is the same class as EventProperties, but created for C++ compatibility.

5.2.7.1 Public fields
- public ChangeEventInfo ch_event;
- public PeriodicEventInfo per_event;
- public ArchiveEventInfo arch_event;

5.2.8 ChangeEventInfo
This class is the same class as fr.esrf.Tango.ChangeEventProp, but created for C++ compatibility.

5.2.8.1 Public fields
- public String rel_change;
- public String abs_change;
- public String[] extensions;

5.2.9 PeriodicEventInfo
This class is the same class as fr.esrf.Tango.PeriodicEventProp, but created for C++ compatibility.
5.2.9.1 Public fields
- public String period;
- public String[] extensions;

ArchiveEventInfo
This class is the same class as fr.esrf.Tango Archive EventProp, but created for C++ compatibility.

5.2.9.2 Public fields
- public String rel_change;
- public String abs_change;
- public String period;
- public String[] extensions;

5.2.10 DbDatum
5.2.10.1 Public fields
- public String name : The data name

5.2.10.2 public methods
5.2.10.2.1 public DbDatum(String name) Constructor for DbDatum Object.
- parameter name : The data name.

5.2.10.2.2 public DbDatum(String name, <Tango type> value) Constructor for DbDatum Object.
- parameter name : The data name.
- parameter value can be one of the Tango type (boolean, short, String[]) and is the value to set the data.

5.2.10.2.3 public void insert(<Tango type> value) Set the data value, where value can be one of the Tango type (boolean, short, String[]).

5.2.10.2.4 public boolean is_empty() This method does not throw exception.
- return true if the value has not been initialized.
5.2.10.2.5 public <TangoType> extract<Tango type>()

Extract the data value.

i.e.:  
public short extractShort(): extract method for a short.  
public short extractDouble(): extract method for a double.  
public String extractString(): extract method for a String.  
public String[] extractStringArray(): extract method for a String array.  
public float[] extractFloatArray(): extract method for a float array.

WARNING: Due to the IDL mapping, the Tango_DEV_LONG is an int for java ! That means that the extractLong method returns an int (and not a long).

5.2.10.3 Example

    // Update device properties.  
    devname = "my/serial/device";  
    DbDatum[] prop;  
    prop = new DbDatum[3];  
    prop[0] = new DbDatum("baudrate", 19200);  
    prop[1] = new DbDatum("parity", "none");  
    prop[2] = new DbDatum("stopbits", 1);  
    dbase.put_property(devname, prop);

5.2.11 DbAttribute Class

This class use a DbDatum vector associated to an attribute name to manage attribute properties.

5.2.11.1 Public fields

- public String name : The attribute name.

5.2.11.2 Public methods

5.2.11.2.1 public DbAttribute(String name)

constructor for DbAttribute object.

- parameter name : attribute name.

5.2.11.2.2 public int size()

return the number of properties (size of DbDatum Vector).

5.2.11.2.3 public DbDatum datum(int idx)

Return the DbDatum object at specified index.

- parameter idx : an index into the array.
- Return the DbDatum object at the specified index.
5.2.11.2.4 public DbDatum datum(String name)
Return the DbDatum object for the specified name.

- parameter name : property name.
- Return the DbDatum object for the specified name.

5.2.11.2.5 public boolean is_empty(String name)
Return true if the property specified is not defined.

- parameter name : property name.
- Return true if the property specified is not defined.

5.2.11.2.6 public String get_value(String name)
Return the property specified value as String.

- parameter name : property name.
- Return the property specified value as String.

5.2.11.2.7 public String[] get_property_list()
Return the list of property names defined in this class.

5.2.11.2.8 public void add(String name, String value)
Add a new property (name and value) in DbAttribute object.

- parameter name : property name
- parameter value : property value

5.2.11.2.9 public void add(String name, short value)
Add a new property (name and value) in DbAttribute object.

- parameter name : property name
- parameter value : property value

5.2.11.2.10 public void add(String name, long value)
Add a new property (name and value) in DbAttribute object.

- parameter name : property name
- parameter value : property value

5.2.11.2.11 public void add(String name, double value)
Add a new property (name and value) in DbAttribute object.

- parameter name : property name
- parameter value : property value
5.2.11.3 Example

```java
String[] attnames = db.get_class_attribute_list("MyClass", "*");
DbAttribute[] attr = db.get_class_attribute_property("MyClass", attnames);
for (int i=0; i<attr.length; i++)
    for (int j=0; j<attr[i].size(); j++)
    {
        DbDatum datum = attr[i].datum(j);
        System.out.println(datum.name + "\t" + datum.extractString());
    }
//
// Or
//
String[] attnames = db.get_class_attribute_list("MyClass", "*");
DbAttribute[] attr = db.get_class_attribute_property("MyClass", attnames);
String label = "Default string";
// Get the label field property
String proname = "Label";
for (int i=0; i<attr.length; i++)
    if (attr[i].is_empty(proname)==false)
        label = attr[i].get_value(proname);
```

5.2.12 DeviceAttribute

5.2.12.1 Public methods

5.2.12.1.1 public DeviceAttribute(AttributeValue attrval)
Device Attribute class constructor.

- Parameter attrval : AttributeValue IDL object (see TANGO IDL documentation).

5.2.12.1.2 public DeviceAttribute(String name, <Tango type> value)
Device Attribute class constructor.

- Parameter name : Attribute name.

- Parameter value can be one of the Tango Attribute type (short, int, double or String).

5.2.12.1.3 public DeviceAttribute(String name, <Tango type array> value, int dim_x, int dim_y)
Device Attribute class constructor.

- Parameter name : Attribute name.

- Parameter value can be one of the Tango Attribute type (short[], int[], double[] or String[]).

- Parameter dim_x : array dimension in X.

- Parameter dim_y : array dimension in Y.
5.2.12.1.4 public void insert(<Tango type> value)
Set the object value where values can be short, int, double or String.

5.2.12.1.5 public void insert(<Tango type array> value)
Set the object value where values can be short[], int[], double[] or String[].

5.2.12.1.6 public <Tango type> extract<Tango type>()
extract the data value.
   ie:
   - public short extractShort() : extract method for a short
   - public short[] extractShortArray() : extract method for a short array
   - public int extractLong() : extract method for a int (Tango_DEV_LONG).
   - public int[] extractLongArray() : extract method for int (Tango_DEV_LONG) a array.
   - public double extractDouble() : extract method for a double
   - public double[] extractDoubleArray() : extract method for a double array
   - public String extractString() : extract method for a String
   - public String[] extractStringArray() : extract method for a String array

5.2.12.1.7 public int getDimX()
Return the array dimension in X.

5.2.12.1.8 public int getDimY()
Return the array dimension in Y.

5.2.12.1.9 public String getName()
Return the attribute name.

5.2.12.1.10 public AttrQuality getQuality()
return the attribute quality (see TANGO IDL documentation).

5.2.12.1.11 public TimeVal getTimeVal()
return the attribute time value (see TANGO IDL documentation).

5.2.12.1.12 Example

   DeviceAttribute devattr = dev.read_attribute("Current");
   double i = devattr.extractDouble();
   
___
5.2.13 DbDevInfo Class
Device information object.

5.2.13.1 Public fields
- public String name : The device name.
- public String _class : The class name.
- public String server : The server name.

5.2.13.2 Public methods
5.2.13.2.1 public DbDevInfo()
Default constructor for DbDevInfo object.

5.2.13.2.2 public DbDevInfo(String name, String _class, String server)
Constructor for DbDevInfo object with values to set public fields.

5.2.13.3 Example

    // Add a group of devices in the database
    // -----------------------------------------------
    DbDevInfo[] devinfos;
    devinfos = new DbDevInfo[2];
    devinfos[0] = new DbDevInfo("sys/dummy/check3", "Dummy", "Dummy/check3");
    devinfos[1] = new DbDevInfo("sys/dummy/check4", "Dummy", "Dummy/check3");
    dbase.add_server(devinfos[0], devinfos[1]);

5.2.14 DbDevImportInfo class
This class is an object containing the imported device information.

5.2.14.1 Public fields
- public String name : The device name.
- public String ior : IOR connection as String.
- public String version : TANGO protocol version number.
- public boolean exported : true if device is exported.
- public String server : Server name and instance name.

5.2.14.2 Public methods
5.2.14.2.1 public DbDevImportInfo()
Default constructor.
5.2.14.3 Example

```
DbDevImportInfo imp_info = dbase.import_device(devname); System.out.println(imp_info);
```

5.2.15 DbDevExportInfo class

This class is an object containing the exported device information.

5.2.15.1 Public fields

- public String name: the device name.
- public String ior: IOR connection as String.
- public String host: Host name where device will be exported.
- public String version: TANGO protocol version number.
- public boolean exported: true if device is exported.

5.2.15.2 Public methods

5.2.15.2.1 public DbDevExportInfo()

Default constructor.

5.2.15.2.2 public DbDevExportInfo(String name, String ior, String host, String version)

Complete constructor.

5.2.15.3 Example

```
DbDevImportInfo imp_info = dbase.import_device(devname);

DbDevExportInfo exp_info =
    new DbDevExportInfo(devname, "MyServer/domain", imp_info.ior, "corvus", imp_info.version);
dbase.export_device(exp_info);
```

5.3 Asynchronous callback related classes

5.3.1 CallBack class

This class define an object to be called at command_inout, read_attribute or write_attribute asynchronous call reply or when an event is received. The user should implement a class inheriting from this one, where at least one of the following methods must be overloaded to receive callback.
5.3.1.1 Public methods

5.3.1.1.1 public void cmd__ended(CmdDoneEvent evt)
This method is defined as being empty and must be overloaded by the user when the asynchronous
callback model is used. This is the method which is executed when the server reply from a
command_inout is received in both push and pull sub mode.

5.3.1.1.2 public void attr_read(AttrReadEvent evt)
This method is defined as being empty and must be overloaded by the user when the asynchronous
callback model is used. This is the method which is executed when the server reply from a
read_attribute is received in both push and pull sub mode.

5.3.1.1.3 public void attr_written(AttrWrittenEvent evt)
This method is defined as being empty and must be overloaded by the user when the asynchronous
callback model is used. This is the method which is executed when the server reply from a
write_attribute is received in both push and pull sub mode.

5.3.1.1.4 public void push_event(EventData evt)
This is the method which is called by the event system whenever it detects the event for which
the user has subscribed with this callback. Information about the related event is encapsulated in
the EventData argument object.

5.3.2 CmdDoneEvent class
This class is used to pass data to the callback method in asynchronous callback model for command_inout execution.

5.3.2.1 Public fields
- public DeviceProxy device : The DeviceProxy object on which the call was executed.
- public String cmd__name : The command name.
- public DeviceData argout : The command output argument.
- public boolean err : Is true if the request failed, false otherwise.
- publicDeviceInfo errors : The error stack.

5.3.3 AttrReadEvent class
This class is used to pass data to the callback method in asynchronous callback model for read_attribute execution.

5.3.3.1 Public fields
- public DeviceProxy device : The DeviceProxy object on which the call was executed.
- public String[] attr_name : The attribute names.
- public DeviceAttribute[] argout : The read attribute output data.
- public boolean err : Is true if the request failed, false otherwise.
- public DeviceError[] errors : The error stack.
CHAPTER 5. TANGO JAVA API

5.3.4 AttrWrittenEvent class
This class is used to pass data to the callback method in asynchronous callback model for write_attribute execution.

5.3.4.1 Public fields
- \texttt{public DeviceProxy device} : The deviceProxy object on which the call was executed.
- \texttt{public String[] attr_name} : The attribute names.
- \texttt{public boolean err} : Is true if the request failed, false otherwise.
- \texttt{public DevError[] errors} : The error stack.

5.3.5EventData class
This class is used to pass data to the callback method (push_event()) when it is called to react to an event.

5.3.5.1 Public fields
- \texttt{public DeviceProxy device} : the DeviceProxy object on which the subscription command was executed (see DeviceProxy.subscribe_event()).
- \texttt{public String name} : the attribute name for which the subscription was made.
- \texttt{public String event} : the event type that it was for with this attribute ("change", "quality_change", "periodic" or "archive")
- \texttt{public DeviceAttribute attr_value} : the event effective data
- \texttt{public Boolean err} : true if something wrong happened with the event delivery mechanism
- \texttt{public DevError[] errors} : the error stack.

5.4 Devices access

5.4.1 DeviceProxy class

5.4.1.1 Tango database management for Tango device.
The following methods are using database connection and could be used without exported device.

5.4.1.1.1 public DeviceProxy(String devname)
Constructor for a DeviceProxy object.

- \texttt{Parameter devname} : The device name.

The device name could be just the device name (sr/powersupply/dipole) or it can use the URL definition.
\begin{verbatim}
<protocol>://<host_name:port_number>/<device_name><#reference>
\end{verbatim}
For example, it could be:

- tango://gizmo:20000/sr/powersupply/dipole
• tango://spica:5555/test/serial/1#dbase=no
• tango://ct/1

If protocol is not specified, TANGO is the default one.
If host and port are not specified, the $TANGO_HOST environment variable is read.
If reference is not specified, the TANGO database is used for device connection.

5.4.1.1.2 public DeviceProxy(String devname, String hostname, String port)
Constructor for a DeviceProxy object.
• Parameter devname: The device name.
• parameter hostname: name of the host for TANGO database.
• parameter port: Port number (as String) for connection.

5.4.1.1.3 public DbDevImportInfo import_device()
Query the database for the export info of this device.
• Return the information in a DbDevImportInfo.

5.4.1.1.4 public void export_device(DbDevExportInfo devinfo)
Update the export info for this device in the database.
• Parameter devinfo: Device information to export.

5.4.1.1.5 public void add_device(DbDevInfo devinfo)
Add/update this device to the database
• Parameter devinfo: The device name, class and server specified in object.

5.4.1.1.6 String[] get_property_list(String wildcard)
Query the database for a list of class properties for this device.
• parameter wildcard: filter (* matches any character e.g. a*).
• Return the property names in a String array.

5.4.1.1.7 public DbDatum[] get_property(String[] propnames)
Query the database for a list of device properties for this device.
• Parameter propnames: list of property names.
• Return properties in DbDatum objects.

5.4.1.1.8 public DbDatum get_property(String propname)
Query the database for a device property for this device.
• Parameter propname: property name.
• Return property in DbDatum objects.
CHAPTER 5. TANGO JAVA API

// get device properties as from database.
String[] pronames = { "baudrate", "parity", "stopbits"};
DeviceProxy dev = new DeviceProxy("my/serial/device");
prop = dev.get_property(pronames);
if (prop[0].is_empty()==false) baud = prop[0].extractLong();
if (prop[1].is_empty()==false) parity = prop[1].extractString();
if (prop[2].is_empty()==false) stop = prop[2].extractShort();

5.4.1.1.9 public DbDatum[] get_property(DbDatum[] properties)
Query the database for a list of device properties for this device. The property names are specified by the DbDatum array objects.

- Parameter properties : list of property DbDatum objects.
- Return properties in DbDatum objects.

5.4.1.1.10 public void put_property(DbDatum[] properties)
Insert or update a list of properties for this device. The property names and their values are specified by the DbDatum array.

- Parameter properties : Properties names and values array.

5.4.1.1.11 public void delete_property(String[] propnames)
Delete a list of properties for this device.

- Parameter propnames : Property names.

5.4.1.1.12 public void delete_property(String propname)
Delete a property for this device.

- Parameter propname : Property name.

5.4.1.1.13 public void delete_property(DbDatum[] properties)
Delete a list of properties for this device.

- Parameter properties : Property DbDatum objects.

5.4.1.1.14 public void put_attribute_property(DbDatum[] properties)
Insert or update a list of properties for this device attribute. The property names and their values are specified by the DbDatum array.

- Parameter properties : Properties names and values array.

5.4.1.1.15 public void delete_attribute_property(String[] propnames)
Delete a list of properties for this object.

- Parameter propnames : Property names.
5.4.1.1.16  public void delete_attribute_property(String proname)
Delete a property for this object.
  
  • Parameter proname : Property name.

5.4.1.1.17  public void delete_attribute_property(DbDatum[] properties)
Delete a list of properties for this object.
  
  • Parameter properties : Property DbDatum objects.

5.4.1.1.18  public DbDatum[] get_attribute_property(String[] pronames)
Query the database for a list of device attribute properties for this device.
  
  • Parameter pronames : list of property names.
  • Return properties in DbDatum objects.

5.4.1.1.19  public DbDatum get_attribute_property(String proname)
Query the database for a device attribute property for this device.
  
  • Parameter proname : list of property name.
  • Return property in DbDatum object.

5.4.1.1.20  public DbDatum[] get_attribute_property(DbDatum[] properties)
Query the database for a list of device attribute properties for this device. The property names are specified by the DbDatum array objects.
  
  • Parameter properties : list of property DbDatum objects.
  • Return properties in DbDatum objects.

5.4.1.1.21  public void delete_attribute(String attname)
Delete an attribute for this device.
  
  • parameter attname : attribute name.

5.4.1.1.22  public String name()
  
  • Return the device name.

5.4.1.2  The exported device management methods
This class manage Tango device connection. It is an api between user and IDL Device object.

5.4.1.2.1  public int get_timeout_millis()
  
  • Return the value of the timeout in milliseconds.

5.4.1.2.2  public void set_timeout_millis(int nb_millis)
  
  • Set the value of the timeout in milliseconds.
5.4.1.2.3  public set_transparency_reconnection(boolean mode)
Set to true or false the transparency mode. If this mode is true, that means that in case of a
connection lost with the device, the API will try to reconnect the server one time before throwing
an exception.

5.4.1.2.4  public get_transparency_reconnection()
Return the transparency mode.

5.4.1.2.5  public DeviceData command_inout(String command, DeviceData data)
Send a command to the device.
  * Parameter command: Command name to send to the device.
  * Parameter data: argin management object.

```java
DeviceProxy dev = new DeviceProxy("my/serial/device");
// Send a write command to the device
DeviceData argin = new DeviceData();
argin.insert("Hello World!");
dev.command_inout("DevWriteMessage", argin);
// Send a read command to the device
DeviceData argout = dev.command_inout("DevReadMessage", data);
String received = argout.extractString();
System.out.println(received);
```

5.4.1.2.6  public DeviceData command_inout(String command)
Send a command to the device.
  * Parameter device: Device instance to send the command.
  * Parameter command: Command name to send to the device.

```java
DeviceProxy dev = new DeviceProxy("sr/powersupply/dipole");
// Send a DevOn command to the device
dev.command_inout("DevOn");
```

5.4.1.2.7  public String[] black_box(int depth)
The device black box is a circular buffer where the commands are logged.
  * parameter depth: the maximum depth to read in the buffer.

5.4.1.2.8  public int ping()
Execute a ping command to the device.
  * Return the elapsed time for the ping command in micro seconds.
CHAPTER 5. TANGO JAVA API

5.4.1.2.9 public DevInfo info()
Execute an info command to the device.

5.4.1.2.10 public CommandInfo[] command_list_query()
Query the command info list to the device.

```java
DeviceProxy dev = new DeviceProxy("sr/powersupply/dipole");
// Get the command list
CommandInfo[] info = dev.command_list_query;
for (int i=0 ; i<info.length ; i++)
    System.out.print(info[i].cmd_name + "(" + info[i].in_type + ", " + info[i].out_type + ")
```

5.4.1.2.11 public CommandInfo command_list_query()
Query a command info to the device.

```java
DeviceProxy dev = new DeviceProxy("sr/powersupply/dipole");
// Get the command list
CommandInfo info = dev.command_query;
System.out.print(info.cmd_name + "(" + info.in_type + ", " + info.out_type + ")
```

5.4.1.2.12 public String status()
Returns the device status.

5.4.1.2.13 public DevState state()
Return the device state.

5.4.1.2.14 public String adm_name()
Returns the administration device name.

5.4.1.2.15 public String description()
Returns the device description.

5.4.1.2.16 public int get_idl_version()
Returns the IDL version supported for device connection.

5.4.1.3 Attribute methods
5.4.1.3.1 public String[] get_attribute_list()
Query the device for a list of attribute names.

- Return attribute names found in a String array.
5.4.1.3.2 public AttributeInfo[] get_attribute_info()
Get all attributes config from device server.
- Return the config for all attributes. Archive

5.4.1.3.3 public AttributeInfoEx[] get_attribute_info_ex()
Get all attributes config from device server.
- Return the extended config for all attributes. Archive

5.4.1.3.4 public AttributeInfo[] get_attribute_info(String[] attnames)
Get attribute config from device server for specified attributes.
- parameter attnames: attribute names to get config.
- Return the config for attributes.

5.4.1.3.5 public AttributeInfoEx[] get_attribute_info_ex(String[] attnames)
Get attribute config from device server for specified attributes.
- parameter attnames: attribute names to get config.
- Return the extended config for attributes.

5.4.1.3.6 public AttributeInfo get_attribute_info(String attname)
Get the attribute config from device server.
- parameter attname: attribute name to get config.
- Return the config for attribute.

```
AttributeInfo[] ac = dev.get_attribute_info(attributes);
for (int i=0 ; i<attributes.length ; i++)
{
    System.out.println("Attribute: " + ac[i].name);
    System.out.println("writable: " + ac[i].writable);
    System.out.println("data_format: " + ac[i].data_format);
    System.out.println("data_type: " + ac[i].data_type);
    System.out.println("max_dim_x: " + ac[i].max_dim_x);
    System.out.println("max_dim_y: " + ac[i].max_dim_y);
    System.out.println("description: " + ac[i].description);
    System.out.println("label: " + ac[i].label);
    System.out.println("unit: " + ac[i].unit);
    System.out.println("standard_unit: " + ac[i].standard_unit);
    System.out.println("display_unit: " + ac[i].display_unit);
    System.out.println("format: " + ac[i].format);
    System.out.println("min_value: " + ac[i].min_value);
    System.out.println("max_value: " + ac[i].max_value);
    System.out.println("min_alarm: " + ac[i].min_alarm);
    System.out.println("max_alarm: " + ac[i].max_alarm);
}
5.4.1.3.7 public AttributeInfoEx get_attribute_info_ex(String attname)
Get the attribute config from device server.
  • parameter attname : attribute name to get config.
  • Return the extended config for attribute.

5.4.1.3.8 public void set_attribute_info(AttributeConfig[] config)
Set the attribute config to the device.
  • parameter config : attribute config to be set.

5.4.1.3.9 public void set_attribute_info(AttributeConfigEx[] config)
Set the attribute config to the device.
  • parameter config : attribute extended config to be set.

5.4.1.3.10 public DeviceAttribute read_attribute(String attname)
Read attribute specified.
  • parameter attname : attribute name to be read.

    DeviceAttribute devattr = dev.read_attribute("Current");
    System.out.println("\nRead " + devattr.extractDouble() + " on " + devattr.getName());

5.4.1.3.11 public DeviceAttribute read_attribute(String[] attnames)
Read attribute specified.
  • parameter attnames : attribute names to be read.

5.4.1.3.12 public void write_attribute(DeviceAttribute devattr)
Write attribute with new value(s).
  • parameter devattr : attribute name and value to write.

    DeviceAttribute wattr =
    new DeviceAttribute("Current", (double) 7.6543);
    dev.write_attribute(wattr);

5.4.1.3.13 public void write_attribute(DeviceAttribute[] devattr)
Write attributes with new values.
  • parameter devattr : attribute names and values to write.
5.4.1.4 Polling methods.

5.4.1.4.1 public set_source(DevSource src)
Set the device data source.
- Parameter src: new data source (CACHE_DEV, CACHE or DEV).

5.4.1.4.2 public DevSource get_source()
Return the device data source.

5.4.1.4.3 public void poll_command(String cmdname, int period)
Add a command to be polled for the device. If already polled, update its polling period.
- Param cmdname: command name to be polled.
- Param period: polling period in milli seconds.

```java
dev.poll_command("ReadCurrent", 1000);
```

5.4.1.4.4 public void poll_attribute(String atname, int period)
Add an attribute to be polled for the device. If already polled, update its polling period.
- Param atname: attribute name to be polled.
- Param period: polling period in milli seconds.

```java
dev.poll_attribute("Current", 1000);
```

5.4.1.4.5 public void stop_poll_command(String cmdname)
Remove command of polled object list
- Param cmdname: command name to be removed of polled object list.

5.4.1.4.6 public void stop_poll_attribute(String atname)
Remove attribute of polled object list
- Param atname: attribute name to be removed of polled object list.

5.4.1.4.7 public String[] polling_status()
Returns the polling status for the device.

5.4.1.4.8 public DeviceDataHistory[] command_history(String cmdname)
Return the full history for command polled.
- Param cmdname: command name to read polled history
5.4.1.4.9  public DeviceDataHistory[] command_history(String cmdname, int nb)
Return nb data of the history for command polled.

- Param cmdname : command name to read polled history
- Param nb : nb data to read.

```java
DeviceDataHistory[] histo = dev.command_history("IOStri", 10);
for (int i=0 ; i<histo.length ; i++)
{
    // Build measure date and display date and value.
    Date date = new Date(histo[i].getTime());
    System.out.println(date + " - " + histo[i].extractString());
}
```

5.4.1.4.10 public DeviceDataHistory[] attribute_history(String attname)
Return the full history for attribute polled.

- Param attname : attribute name to read polled history.

5.4.1.4.11 public DeviceDataHistory[] attribute_history(String attname, int nb)
Return nb data of the history for attribute polled.

- Param attname : attribute name to read polled history.
- Param nb : nb data to read.

5.4.1.5  Asynchronous command oriented methods
Asynchronous call can be used with two models:

- Polling model : The client send an idl command and check if the reply is arrived.
- Callback model : The reply result will be sent to an object. Callback model has two sub models:
  - push sub model : the result will be sent automatically to the callback object when reply arrives.
  - pull sub model : the result will be sent to the callback object when the client will ask for
    (default mode).

The callback sub model (ApiDefs.PUSH_CALLBACK or ApDefs.PUSH_CALLBACK) need to be selected before calling this method (see ApiUtil.set_async_cb_sub_model() method).

WARNING: Do not use the same DeviceData object as input parameter for many
command_mout_async() before the reply has been received. You risk trouble to
overwrite object before it will be really sent.
5.4.1.5.1  public int command_inout_async(String cmdname)
Execute asynchronously (pooling model) a command on a device which takes no input argument.
- Parameter cmdname : Command name to send to the device.
- Returns an asynchronous call identifier which is needed to get the command result.

5.4.1.5.2  public int command_inout_async(String cmdname, boolean forget)
Execute asynchronously (pooling model) a command on a device which takes no input argument and forget response if forget is true.
- Parameter cmdname : Command name to send to the device.
- Parameter forget : if true, the command reply will be forgotten.
- Returns an asynchronous call identifier which is needed to get the command result or 0 if forget is true.

5.4.1.5.3  public int command_inout_async(String cmdname, DeviceData argin)
Execute asynchronously (pooling model) a command on a device with input argument.
- Parameter cmdname : Command name to send to the device.
- Parameter argin : Input command argument.
- Returns an asynchronous call identifier which is needed to get the command result.

```java
data - new DeviceData();
data.insert("Hello World");
int id = dev.command_inout_async("WriteMessage", data);
```

5.4.1.5.4  public int command_inout_async(String cmdname, DeviceData argin, boolean forget)
Execute asynchronously (pooling model) a command on a device with input argument and forget response if forget is true.
- Parameter cmdname : Command name to send to the device.
- Parameter argin : Input command argument.
- Parameter forget : if true, the command reply will be forgotten.
- Returns an asynchronous call identifier which is needed to get the command result or 0 if forget is true.

5.4.1.5.5  public DeviceData command_inout_reply(int id)
Check if the answer of an asynchronous command_inout is arrived (polling model).
- If the reply is arrived and if it is a valid reply, it is returned to the caller in a DeviceData object.
- If the reply is an exception, it is re-thrown by this call.
- If the answer is not arrived, an AsyncReplyNotArrived exception is thrown.
- Parameter id : Asynchronous call identifier returned by command_inout_async method.
5.4.1.5.6 public DeviceData command_inout_reply(int id, int timeout)
Check if the answer of an asynchronous command_inout is arrived (polling model).
If the reply is arrived and if it is a valid reply, it is returned to the caller in a DeviceData object.
If the reply is an exception, it is re-thrown by this call.
If the answer is not arrived, the call will wait for the time specified by timeout before reply or throws an AsynReplyNotArrived exception is thrown.

- Parameter id : Asynchronous call identifier returned by command_inout_asynch method.
- Parameter timeout : time to wait reply in milliseconds.

DeviceData data = new DeviceData();
data.insert(setpoint);
int id = dev.command_inout_asynch("SetReadCurrent", data);
try {
   // will wait reply 200 ms if reply not yet arrived
   DeviceData argout = dev.command_inout_reply(id, 200);
displayCurrent(argout);
} catch (AsynReplyNotArrived e) {
   Except.print_exception(e);
} catch (DevFailed e) {
   Except.print_exception(e);
}

5.4.1.5.7 public void command_inout_asynch(String cmdname, CallBack cb)
Execute asynchronously (callback model) a command on a device without input argument. The command reply will be sent to the CallBack object.

- Parameter cmdname : Command name to send to the device.
- Parameter cb : CallBack object to send the command result in a CmdDoneEvent object.

5.4.1.5.8 public void command_inout_asynch(String cmdname, DeviceData argin, CallBack cb)
Execute asynchronously (callback model) a command on a device with input argument. The command reply will be sent to the CallBack object.

- Parameter cmdname : Command name to send to the device.
- Parameter argin : Input command argument.
- Parameter cb : CallBack object to send the command result in a CmdDoneEvent object.
class MyCallback extends CallBack
{
    public void cmdEnded(CmdDoneEvent evt)
    {
        if (evt.err)
            Exception.print_exception(evt.errors);
        else
            System.out.println("The command " + evt.cmdname + " returns " +
                              evt.argout.extracDouble());
    }
}

class MyClass
{
    public set_read_current(double setpoint)
    {
        :
        :
        :
        // The callback will called at reply
        MyCallback my_cb = new MyCallback();
        ApiUtil.set_async_cb_sub_model(ApiDefs.PUSH_CALLBACK);
        DeviceData data = new DeviceData();
        data.insert(setpoint);
        dev.command_inout_async("SetReadCurrent", data, my_cb);
        :
    }
}

5.4.1.6 Asynchronous attribute related methods

Asynchronous call can be used with two models:

- Polling model: The client send an idl command and check if the reply is arrived.
- Callback model: The reply result will be sent to an object. Callback model has two sub models:
  - push sub model: the result will be sent automatically to the callback object when reply arrives.
  - pull sub model: the result will be sent to the callback object when the client will ask for (default mode).

The callback sub model (ApiDefs.PULL_CALLBACK or ApiDefs.PUSH_CALLBACK) need to be selected before calling this method (see ApiUtil.set_async_cb_sub_model() method).
5.4.1.6.1  public int read_attribute_async(String atname)

Read asynchronously (polling model) a single attribute. This call returns an asynchronous call identifier which is needed to get attribute value.

- Parameter atname : attribute name to read.
- Returns an asynchronous call identifier which is needed to get the attribute result.

5.4.1.6.2  public int read_attribute_async(String[] attnames)

Read asynchronously (polling model) the list of specified attributes. This call returns an asynchronous call identifier which is needed to get attribute value.

- Parameter attnames : attribute names to read
- Returns an asynchronous call identifier which is needed to get the attribute result

5.4.1.6.3  public DeviceAttribute[] read_attribute_reply(int id)

Check if the answer of an asynchronous read_attribute is arrived (polling model).

If the reply is arrived and if it is a valid reply, it is returned to the caller in a DeviceAttribute array.

If the reply is an exception, it is re-thrown by this call.

If the answer is not arrived, throws an AsynReplyNotArrived exception is thrown.

- Parameter id : Asynchronous call identifier returned by read_attribute_asynch method.

5.4.1.6.4  public DeviceAttribute[] read_attribute_reply(int id, int timeout)

Check if the answer of an asynchronous read_attribute is arrived (polling model).

If the reply is arrived and if it is a valid reply, it is returned to the caller in a DeviceAttribute array.

If the reply is an exception, it is re-thrown by this call.

If the answer is not arrived, the call will wait for the time specified by timeout before reply or throws an AsynReplyNotArrived exception is thrown.

- Parameter id : Asynchronous call identifier returned by read_attribute_asynch method.
- Parameter timeout : time to wait reply in milliseconds.

5.4.1.6.5  public void read_attribute_asynch(String atname, CallBack cb)

Read asynchronously (callback model) a read_attribute_asynch reply. The read_attribute reply will be sent to the CallBack object.

- Parameter atname : attribute name to read.
- Parameter cb : CallBack object to send the read_attribute result in a AttrReadEvent object.

```java
class MyCallback extends CallBack
{
  public void attr_read(AttrReadEvent evt)
  {
    if (evt.err)
      Exception.print_exception(evt.errors);
```
CHAPTER 5. TANGO JAVA API

else
    System.out.println("The attribute " + evt.attr_names[0] + " returns " +
    evt.argout[0].extractDouble());
}
}
class MyClass
{
    : : :
    : : :
    public read_current()
    {
        // The callback will automatically called
        ApiUtil.set_async_cb_sub_model(ApiDefs.PUSH_CALLBACK);
        dev.read_attribute_asynch("Current", MyCallback);
    }
    : : :
    : : :
    : : :
}

5.4.1.6.6 public void read_attribute_asynch(String[] attnames, CallBack cb)
Read asynchronously (callback model) a read_attribute_asynch reply. The read_attribute reply
will be sent to the CallBack object.

- Parameter attnames : array of attribute names to read.
- Parameter cb : CallBack object to send the read_attribute result in a AttrReadEvent object.

5.4.1.6.7 public int write_attribute_asynch(DeviceAttribute attr)
Write asynchronously (polling model) a single attribute.

- Parameter attr : attribute data to write (name, value...)

5.4.1.6.8 public int write_attribute_asynch(DeviceAttribute attr, boolean forget)
Write asynchronously (polling model) a single attribute and forget reply if forget is true.

- Parameter attr : attribute data to write (name, value...).
- Parameter forget : if true, the command reply will be forgotten.
- Returns an asynchronous call identifier which is needed to get the attribute result or 0 if
  forget is true.

5.4.1.6.9 public int write_attribute_asynch(DeviceAttribute[] attr)
Write asynchronously (polling model) a list of attributes.

- Parameter attr : attribute list to write (name, value...)

5.4.1.6.10 public int write_attribute_asynch(DeviceAttribute attr, boolean forget)
Write asynchronously (polling model) a list of attributes and forget reply if forget is true.
5.4.1.6.11 public void write_attribute_reply(int id)
Check if the answer of an asynchronous write_attribute is arrived (polling model).
   If the reply is arrived and if it is a valid reply, the call is returned.
   If the reply is an exception, it is re-thrown by this call.
   If the answer is not arrived, throws an AsynReplyNotArrived exception is thrown.
   • Parameter id : Asynchronous call identifier returned by write_attribute_asynch method.

5.4.1.6.12 public void write_attribute_reply(int id, int timeout)
Check if the answer of an asynchronous write_attribute is arrived (polling model).
   If the reply is arrived and if it is a valid reply, the call is returned.
   If the reply is an exception, it is re-thrown by this call.
   If the answer is not arrived, the call will wait for the time specified by timeout before reply or
   throws an AsynReplyNotArrived exception is thrown.
   • Parameter id : Asynchronous call identifier returned by write_attribute_asynch method.
   • Parameter timeout : time to wait reply in milliseconds.

5.4.1.6.13 public void write_attribute_asynch(DeviceAttribute attr, CallBack cb)
Write asynchronously (callback model) a write_attribute_asynch reply. The write_attribute reply
will be sent to the CallBack object.
   • Parameter attr : attribute data to write (name, value...)
   • Parameter cb : CallBack object to send the write_attribute result in a AttrWrittenEvent object.

5.4.1.6.14 public void write_attribute_asynch(DeviceAttribute[] attr, CallBack cb)
Write asynchronously (callback model) a write_attribute_asynch reply. The write_attribute reply
will be sent to the CallBack object.
   • Parameter attr : attribute list to write (name, value...).
   • Parameter cb : CallBack object to send the write_attribute result in a AttrWrittenEvent object.

5.4.1.7 Miscellaneous asynchronous related methods
5.4.1.7.1 public int pending_asynch_call(int type_req)
Returns number of device asynchronous pending requests.
   • Parameter type_req :
     - ApiDefs.POLLING : returns device polling model pending asynchronous request num-
       ber.
CHAPTER 5. TANGO JAVA API

- ApiDefs CALLBACK: returns device **callback** model pending asynchronous request number.
- ApiDefs ALL _ASYNCH: returns **all** device pending asynchronous request number.

### 5.4.1.7.2 public void get_asynch_replies()

Fire all callback methods for device asynchronous requests with already arrived replied.

```java
class MyCallback extends CallBack {
    public void cmd_started(CmdDoneEvent evt) {
        if (evt.err) {
            Exception.print_exception(evt.errors);
        }
        else {
            System.out.println("The command " + evt.cmdname + " returns " +
            evt.argout.extractDouble());
        }
    }
}
class MyClass {
    :
    :
    :
    :
    :
    : public set_read_current(double setpoint) {
    :
    :
    :
    :
    :
    :
    :
    :
    // The callback will triggered later
    ApiUtil.set_async_ch_sub_model(ApiDefs.PULL_CALLBACK);
    DeviceData data = new DeviceData();
    data.insert(setpoint);
    dev.command_inout_asynch("SetReadCurrent", data, MyCallback);
    :
    :
    :
    :
    :
    // Trigger callback now.
    dev.get_asynch_replies();
    }
    :
    :
    }
}
```

### 5.4.1.7.3 public void get_asynch_replies(int timeout)

Fire all callback methods for device asynchronous requests with already arrived replied or arrived before the end of timeout.

- Parameter **timeout**: number of milliseconds to wait reply.
5.4.1.8 Event related methods

5.4.1.8.1 public int subscribe_event(String attr_name, int event, EventCallBack callback, String[] filters)

Notifies the event system that client is interested in some type of event concerning a given attribute.

- Parameter attr_name : the device attribute name which will be sent as an event
- Parameter event : the event type for which we subscribe (one of Tango constants : CHANGE_EVENT, QUALITY_EVENT, PERIODIC_EVENT, ARCHIVE_EVENT)
- Parameter callback : EventCallBack object which will receive the event
- Parameter filters : filters on events (Not implemented in release 4.0.0)
- Returns an event identifier which is need to unsubscribe from the event.

5.4.1.8.2 public void unsubscribe_event(int event_id)

Notifies the event system that client is no more interested in a given event for which it has subscribed before.

- Parameter event_id : the event identifier that was returned when subscription was made for this event.

5.4.1.9 Logging related methods

5.4.1.9.1 public void add_logging_target(String target)

Adds a new logging target to the device. Supported target types are: console, file and device. For a device target, the target parameter must contain the name of a log consumer device (as defined in A.7). For a file target, target is the full path to the file to log to. If omitted, the device’s name is used to build the file name (which is something like domain_family_member.log). Finally, target name is ignored in case of a console target and can be omitted.

5.4.1.9.2 public void remove_logging_target(String target_type, String target_name)

Removes a logging target from the device’s target list. Supported target types are: console, file and device. For a device target, the target_name contains the name of a log consumer device (as defined in ). For a file target, target_name is the full path to the file to remove. If omitted, the default log file is removed. Finally, target_name is ignored in case of a console target and can be omitted.

If target_name is set to "**", all targets of the specified target_type are removed.

5.4.1.9.3 public String[] get_logging_target()

Returns an array of string containing the current device’s logging targets. Each vector element has the following format: target_type::target_name. An empty array is returned is the device has no logging targets.

5.4.1.9.4 public void set_logging_level(int level)

Set the device’s logging level:

- ApiDefs.LOGGING_OFF = 0;
CHAPTER 5. TANGO JAVA API

- ApiDefs.LOGGING_FATAL = 1;
- ApiDefs.LOGGING_ERROR = 2;
- ApiDefs.LOGGING_WARNING = 3;
- ApiDefs.LOGGING_INFO = 4;
- ApiDefs.LOGGING_DEBUG = 5;

5.4.1.9.5 public int get_logging_level()

Returns the device's logging level:

- ApiDefs.LOGGING_OFF = 0;
- ApiDefs.LOGGING_FATAL = 1;
- ApiDefs.LOGGING_ERROR = 2;
- ApiDefs.LOGGING_WARNING = 3;
- ApiDefs.LOGGING_INFO = 4;
- ApiDefs.LOGGING_DEBUG = 5;

5.4.1.9.6 Logging example

```java
// Set a logging target and level to the device.
DeviceProxy dev = new DeviceProxy(devname);
dev.add_logging_target("file", "/tmp/logging_device");
dev.set_logging_level(ApiDefs.LOGGING_INFO);
```

5.4.1.10 TACO Device access

An interface with TACO world has been implemented for basic argument types and commands. It uses a JNI (Java Native Interface) class to load a C++ library called libtaco.so. That means that your LD_LIBRARY_PATH environment variable must be set to found this library and the taco libraries (libdbapi.so, libdsapi.so, libdszdr.so, libdsapi.so), and the NETHOST must be set the host where the TACO database is running.

To specify that your device is a TACO device, the device name must be preceded by "taco:“, when the DeviceProxy constructor is called.

5.4.1.10.1 public DeviceData command_inout(String command, DeviceData data)

Send a command to the device as a TANGO device.

- Parameter command: Command name to send to the device.
- Parameter data: argin management object.
DeviceProxy  dev = new DeviceProxy("taco:my/serial/device");

// Send a write command to the device
DeviceData  argin = new DeviceData();
argin.insert("Hello World!");
dev.command_inout("DevWriteMessage", argin);

// Send a read command to the device
DeviceData  argout = dev.command_inout("DevReadMessage", data);
String  received = argout.extractString();
System.out.println(received);

5.4.1.10.2 public DeviceData command_inout(String command)
Send a command to the device as a TANGO device.

- Parameter command : Command name to send to the device.

DeviceProxy  dev = new DeviceProxy("taco:sr/powersupply/dipole");
// Set the power supply on.
dev.command_inout("On");

5.4.1.10.3 Supported arguments for command_inout methods.

<table>

5.4.1.10.4 public DevCmdInfo[] command_list_query()
Execute a command_list_query command to the device as a TANGO device.

DevCmdInfo[]  cmdInfo = tacodev.command_list_query();
for (int i=0; i<cmdInfo.length ; i++)
    System.out.println("" + cmdInfo[i].cmd_name + "(" +
        cmdInfo[i].in_type + "," +
        cmdInfo[i].out_type + ")");
WARNING:

- The cmd_name could be null if the command name has not been found in database for the TACO command code.
- The in_type or/and out_type could be set to -1 if the TACO argument type is not supported.

5.4.1.10.5  public int get_timeout_millis()

- Return the value of the timeout in milliseconds as TANGO device.

5.4.1.10.6  public String status()

Returns the device status.

5.4.1.10.7  public DevState state()

Return the device state.

5.4.1.10.8  public String[] dev_inform()

Read device information (TACO specific). The array index are:

- 0: Device name.
- 1: Class name.
- 2: Device type.
- 3: Server name.
- 4: Server host.

5.4.1.10.9  public void dev_rpc_protocol(int mode)

Set the RPC mode for further commands.

- parameter mode: ApiDefs.D_TCP or ApiDefs.D_UDP.

5.4.1.10.10 public String[] get_attribute_list(String wildcard)

Query the TACO device server for a list of attribute names for the specified object.

- parameter wildcard: filter (* matches any character e.g. a*)
- Return attribute names found in a String array.

5.4.1.10.11 public AttributeConfig[] get_attribute_config(String[] atnames)

Get the TACO signals config from device server as TANGO attributes (use DevGetSigConfig command).

- parameter atnames: attribute names to get config.
- Return the config for attributes.
5.4.1.10.12 public AttributeConfig get_attribute_config(String attname)

Get the TACO signal config from device server as a TANGO attribute (use DevGetSigConfig command).

- parameter attname: attribute name to get config.
- Return the config for attribute.

```java
AttributeConfig[] ac = dev.get_attribute_config(attributes);
for (int i=0; i<attributes.length; i++)
{
    System.out.println("Attribute: " + ac[i].name);
    System.out.println("writable: " + ac[i].writable);
    System.out.println("data_format: " + ac[i].data_format);
    System.out.println("data_type: " + ac[i].data_type);
    System.out.println("max_dim_x: " + ac[i].max_dim_x);
    System.out.println("max_dim_y: " + ac[i].max_dim_y);
    System.out.println("description: " + ac[i].description);
    System.out.println("label: " + ac[i].label);
    System.out.println("unit: " + ac[i].unit);
    System.out.println("standard_unit: " + ac[i].standard_unit);
    System.out.println("display_unit: " + ac[i].display_unit);
    System.out.println("format: " + ac[i].format);
    System.out.println("min_value: " + ac[i].min_value);
    System.out.println("max_value: " + ac[i].max_value);
    System.out.println("min_alarm: " + ac[i].min_alarm);
    System.out.println("max_alarm: " + ac[i].max_alarm);
}
```

5.4.1.10.13 public DeviceAttribute read_attribute(String attname)

Read TACO signal specified as a TANGO attribute.

- parameter attname: attribute name to be read.

```java
DeviceAttribute devattr = dev.read_attribute("Current");
System.out.println("mRead" + devattr.extractDouble() + " on " + devattr.getName());
```

5.4.1.10.14 public DeviceAttribute read_attribute(String[] attnames)

Read TACO signals specified as TANGO attributes.

- parameter attnames: attribute names to be read.

5.4.2 AttributeProxy class

This class manage an attribute as a remote object and it contains a DeviceProxy object. That means that a new connection is created for each AttributeProxy created.

See DeviceProxy - Attributes methods chapter (5.4.1.3) for more details.
5.4.2.0.15 public AttributeProxy(String attname)
AttributeProxy class constructor.

- parameter attname: full attribute name containing the device name and the attribute
  name (e.g. sr/ps/1/current create an AttributeProxy object for attribute current on de-
  vice sr/ps/1).

5.4.2.1 Attribute access related methods
5.4.2.1.1 public String fullName()
Return the full attribute name as specified for constructor().

5.4.2.1.2 public String name()
Return the attribute name (last field of the the name specified for constructor).

5.4.2.1.3 public DbAttribute get_property()
Query the database for a list of device attribute properties for this device.

```
AttributeProxy att = new AttributeProxy("sr/ps/1/current");
DbAttribute db_att = att.get_property();
for (int i = 0; i < db_att.size(); i++)
{
    DbDatum datum = db_att.datum(i);
    System.out.println(datum.name + " : " + datum.extractString());
}
```

5.4.2.1.4 public void put_property(DbDatum property)
Insert or update an attribute property for this device.

- parameter property: The property name and its value.

5.4.2.1.5 public void put_property(DbDatum[] properties)
Insert or update an attribute properties for this device.

- parameter properties: The property names and their values.

5.4.2.1.6 public void delete_property(String propname)
Delete a property for this object.

- parameter propname: property's name to be deleted.

5.4.2.1.7 public void delete_property(String[] propnames)
Delete properties for this object.

- parameter propnames: properties' names to be deleted.
5.4.2.18 public AttributeInfo get_info()
Get the attribute's configuration.

5.4.2.19 public AttributeInfoEx get_info_ex()
Get the attribute's extended configuration.

5.4.2.10 public void set_info_ex(AttributeInfo attr)
Set the attribute's configuration.

5.4.2.11 public void set_info_ex(AttributeInfoEx attr)
Set the attribute's extended configuration.

5.4.2.12 public DeviceAttribute read()
Read the attribute value.

```
AttributeProxy att - new AttributeProxy("sr/ps/1/current");
DeviceAttribute da - att.read();
System.out.println(att.name() + " : " + da.extractDouble());
```

5.4.2.13 public void write(DeviceAttribute devattr)
Write the attribute value for the specified device.

- parameter devattr : attribute name and value.

```
AttributeProxy att - new AttributeProxy("sr/ps/1/current");
DeviceAttribute da - new DeviceAttribute(att.name(),(double)512.427);
att.write(da);
```

5.4.2.14 public DeviceDataHistory[] history(int nb)
Return the history for attribute polled.

- parameter nb : number of data to read in history.

5.4.2.15 public DeviceDataHistory[] history()
Return the full history for attribute polled.

5.4.2.16 public void poll(int period)
Add this attribute to be polled for the device. If already polled, update its polling period.

- parameter period : polling period in milliseconds.
5.4.2.1.17 public void stop_poll()
Remove attribute of polled object list.

5.4.2.2 Asynchronous call related methods.
See DeviceProxy - Asynchronous call related methods chapter (5.4.1.6) for more details.

5.4.2.2.1 public int read_asynch()
Asynchronous read method.

5.4.2.2.2 public void read_asynch(CallBack cb)
Asynchronous read method using callback for reply.

- parameter cb : a CallBack object instance called at end of reading.

5.4.2.2.3 public DeviceAttribute[] read_reply(int id)
Read Asynchronous read_attribute reply.

- parameter id : asynchronous call id (returned by read_asynch).

5.4.2.2.4 public DeviceAttribute[] read_reply(int id, int timeout)
Read Asynchronous read_attribute reply.

- parameter id : asynchronous call id (returned by read_asynch).
- parameter timeout : number of milliseconds to wait reply before throw an exception.

5.4.2.2.5 public int write_asynch(DeviceAttribute attr)
Asynchronous write_attribute.

- parameter attr : Attribute value (name, writing value...).

5.4.2.2.6 public int write_asynch(DeviceAttribute attr, boolean forget)
Asynchronous write_attribute.

- parameter attr : Attribute value (name, writing value...).

- parameter forget : forget the response if true.

5.4.2.2.7 public void write_asynch(DeviceAttribute attr, CallBack cb)
Asynchronous write_attribute using callback for reply.

- parameter attr : Attribute value (name, writing value...).

- parameter cb : a CallBack object instance called at end of writing.

5.4.2.2.8 public void write_reply(int id)
check for Asynchronous write reply.

- param id asynchronous call id (returned by read_asynch).
5.4.2.2.9 public void write_reply(int id)
check for Asynchronous write reply.
  - parameter id : asynchronous call id (returned by write_asynch).

5.4.2.2.10 public void write_reply(int id, int timeout)
check for Asynchronous write reply.
  - parameter id : asynchronous call id (returned by write_asynch).
  - parameter timeout : number of milliseconds to wait reply before throw an exception.

5.4.2.3 Events related methods
See DeviceProxy - Events related methods chapter (5.4.1.8) for more details.

5.4.2.3.1 public int subscribe_event(int event, EventCallBack callback, String[] filters)
Subscribe to an event.
  - Parameter event : the event type for which we subscribe (one of Tango constants : CHANGE_EVENT, QUALITY_EVENT, PERIODIC_EVENT, ARCHIVE_EVENT)
  - Parameter callback : EventCallBack object which will receive the event
  - Parameter filters : filters on events (Not implemented in release 4.0.0)
  - Returns an event identifier which is need to unsubscribe from the event.

5.4.2.3.2 public void unsubscribe_event(int event_id)
Notifies the event system that client is no more interested in a given event for which it has subscribed before.
  - Parameter event_id : the event identifier that was returned when subscription was made for this event.

5.5 Utility classes

5.5.1 ApiUtil class
This class manage a vector of Database object created. The goal of this class is to have ONLY ONE connection on a TANGO database for a host. This class manage also some utilities for users (e.g. asynchronous call or state names).

5.5.1.0.3 static public Database get_db_obj()
If no Database object has been created before (no connection done) for the host specified in $TANGO_HOST, it create and return a new Database object. If a Database object has been already created, it just returns this Database object.
5.5.1.0.4 static public Database get_db_obj(String hostname, String port)

If no Database object has been created before (no connection done) for the host specified by hostname and port parameters, it creates and returns a new Database object. If a Database object has been already created for this host, it just returns this Database object.

- parameter hostname : name of the host for TANGO database.
- parameter port : Port number (as String) for connection.

5.5.1.0.5 static public int pending_asynch_call(int type_req)

Returns number of asynchronous pending requests (any device).

- Parameter type_req :
  - ApiDefs.POLLING : returns polling model pending asynchronous request number.
  - ApiDefs.CALLBACK : returns callback model pending asynchronous request number.
  - ApiDefs.ALLASYNCH : returns all pending asynchronous request number.

5.5.1.0.6 static public void get_asynch_replies()

Fire all callback methods for asynchronous requests with already arrived replied or arrived before the end of timeout.

5.5.1.0.7 static public void get_asynch_replies(int timeout)

Fire all callback methods for asynchronous requests with already arrived replied or arrived before the end of timeout.

- Parameter timeout : number of milliseconds to wait reply.

5.5.1.0.8 static public void set_asynch_cb_sub_model(int model)

Set the asynchronous callback sub-model between the pull and push sub-model.

- Parameter model :
  - ApiDefs.PULL_CALLBACK : the pull callback sub-model.
  - ApiDefs.PUSH_CALLBACK : the push callback sub-model.

By default, all Tango client using asynchronous callback model are in pull callback sub-model.
NOTE: in push sub-model, a separate thread is spawned to deal with server replies.

ApIUtil.set_asynch_cb_sub_model(ApiDefs.PUSH_CALLBACK);

5.5.1.0.9 static public int get_asynch_cb_sub_model()

Returns the asynchronous callback sub-model.
5.5.1.0.10  static public String stateName(DevState state)
Returns the associated name of a state to a DevState parameter.

    System.out.println("device is " + ApiUtil.stateName(dev.state()));

5.6  Multiple devices access

5.6.1  The Group class

5.6.1.1  Constructor

5.6.1.1.1  Group (String name)
Instanciate an empty group. The group name allows retrieving a sub-group in the hierarchy.
    See also: Group.get_group.

5.6.1.2  Group Management Related Methods

5.6.1.2.1  void add (Group group)
Attaches a (sub)group.
    This method does nothing if the specified group if already attached (i.e. it is silently ignored).
    See also: all other forms of Group.add.

5.6.1.2.2  void add (String pattern)
Attaches any device which name matches the specified pattern.
    The pattern parameter can be a simple device name or a device name pattern (e.g. domain_*/
    family/member_*)
    This method first asks the Tango database the list of device names matching the pattern.
    Devices are then attached to the group in the order in which they are returned by the database.
    Any device already present in the hierarchy (i.e. a device belonging to the group or to one of
    its subgroups) is silently ignored.
    See also: all other forms of Group.add.

5.6.1.2.3  void add ([String[] patterns])
Attaches any device which name matches one of the specified patterns.
    The patterns parameter can be an array of device names and/or device name patterns.
    This method first asks the Tango database the list of device names matching one the patterns.
    Devices are then attached to the group in the order in which they are returned by the database.
    Any device already present in the hierarchy (i.e. a device belonging to the group or to one of
    its subgroups), is silently ignored.
    See also: all other forms of Group.add.

5.6.1.2.4  void remove (String pattern, boolean fwd)
Removes any group or device which name matches the specified pattern.
    The pattern parameter can be a group name, a device name or a device name pattern (e.g
    domain_*/family/member_*).
Since we can have groups with the same name in the hierarchy, a group name can be fully qualified to specify which group should be removed. Considering the following group:

```
  -> gauges
    | -> cell-01
    |   |-> penning
    |   |-> ...
    | -> pirani
    |-> ...
  -> cell-02
    | -> penning
    |   |-> ...
    | -> pirani
    |-> ...
  -> cell-03
    | -> ...
    |-> ...
```

A call to gauges.remove("penning") will remove any group named "penning" in the hierarchy while gauges.remove("gauges.cell-02.penning") will only remove the specified group.

If `fwd` is set to true, the remove request is also forwarded to subgroups. Otherwise, it is only applied to the local set of elements. For instance, the following code remove any stepper motor in the hierarchy:

```
  root_group.remove("*/stepper_motor/*");
```

See also: all other forms of Group.remove.

### 5.6.1.2.5 void remove (String[] patterns, bool fwd)

Removes any group or device which name matches the specified patterns.

The `patterns` parameter can be an array of group names and/or device names and/or device name patterns.

Since we can have groups with the same name in the hierarchy, a group name can be fully qualified to specify which group should be removed. See previous method for details.

If `fwd` is set to true, the remove request is also forwarded to subgroups. Otherwise, it is only applied to the local set of elements.

See also: all other forms of Group.remove.

### 5.6.1.2.6 void remove_all ()

Removes all elements in the group. After such a call, the group is empty.

See also: all forms of Group.remove.

### 5.6.1.2.7 boolean contains (String pattern, boolean fwd)

Returns true if the hierarchy contains groups and/or devices which name matches the specified `pattern`. Returns false otherwise.

The pattern can be a fully qualified or simple group name, a device name or a device name pattern.

If `fwd` is set to true, the request is also forwarded to subgroups. Otherwise, it is only applied to the local set of elements.

See also: Group::get_device, Group::get_group.
5.6.1.2.8 DeviceProxy get_device (String device_name)

Returns a reference to the specified device or null if there is no device by that name in the group. See the TangoApi.DeviceProxy class documentation for details.

The request is systematically forwarded to subgroups (i.e. if no device named device_name could be found in the local set of devices, the request is forwarded to subgroups).

See also: other form of Group.get_device, Group.get_size, Group.get_group, Group.contains.

5.6.1.2.9 DeviceProxy get_device (int idx)

Returns a reference to the "idx-th" device in the hierarchy or null if the hierarchy contains less than "idx" devices. See the TangoApi.DeviceProxy class documentation for details.

The request is systematically forwarded to subgroups (i.e. if the local set of devices contains less than "idx" devices, the request is forwarded to subgroups).

See also: other form of Group.get_device, Group.get_size, Group.get_group, Group.contains.

5.6.1.2.10 Group get_group (String group_name)

Returns a reference to the specified group or null if there is no group by that name. The group_name can be a fully qualified name.

Considering the following group:

```
-+ gauges
  | -+ cell-01
  |   | -+ penning
  |   |   | -+ ...
  |   | -+ pirani
  |   |   | -+ ...
  | -+ cell-02
  |   | -+ penning
  |   |   | -+ ...
  |   | -+ pirani
  |   |   | -+ ...
  | -+ cell-03
  |   | -+ ...
  |   | -+ ...
```

A call to gauges.get_group("penning") returns the first group named "penning" in the hierarchy (i.e. gauges.cell-01.penning) while gauges.get_group("gauges.cell-02.penning") returns the specified group.

The request is systematically forwarded to subgroups (i.e. if no group named group_name could be found in the local set of elements, the request is forwarded to subgroups).

See also: Group.get_device, Group.contains.

5.6.1.2.11 int get_size (boolean fwd)

Return the number of devices in the hierarchy (respectively the number of device in the group) if the fwd option is set to true (respectively set to false).

5.6.1.2.12 String[] get_device_list (boolean fwd)

Returns the list of devices currently in the hierarchy.

If fwd is set to true the request is forwarded to subgroups. Otherwise, it is only applied to the local set of devices.

Considering the following hierarchy:
CHAPTER 5. TANGO JAVA API

    g2.add("my/device/04"); g2.add("my/device/05");
    g4.add("my/device/08"); g4.add("my/device/09");
    g3.add("my/device/06");
    g3.add(g4);
    g3.add("my/device/07");
    g1.add("my/device/01");
    g1.add(g2);
    g1.add("my/device/03");
    g1.add(g3);
    g1.add("my/device/02");

The list content depends on the value of the forward option. If set to true, the results will be organized as follows:

    String[] dl = g1.get_device_list(true);

- dl[0] contains "my/device/01" which belongs to g1
- dl[1] contains "my/device/04" which belongs to g1.g2
- dl[2] contains "my/device/05" which belongs to g1.g2
- dl[3] contains "my/device/03" which belongs to g1
- dl[4] contains "my/device/06" which belongs to g1.g3
- dl[5] contains "my/device/08" which belongs to g1.g3.g4
- dl[6] contains "my/device/09" which belongs to g1.g3.g4
- dl[7] contains "my/device/07" which belongs to g1.g3
- dl[8] contains "my/device/02" which belongs to g1

If the forward option is set to false, the results are:

    String[] dl = g1.get_device_list(false);

- dl[0] contains "my/device/01" which belongs to g1
- dl[1] contains "my/device/03" which belongs to g1
- dl[2] contains "my/device/02" which belongs to g1

5.6.1.3 "A la" DeviceProxy Methods

5.6.1.3.1 boolean ping (boolean fwd)

Ping all devices in a group. This method returns true if all devices in the group are alive, false otherwise.

If fwd is set to true, the request is also forwarded to subgroups. Otherwise, it is only applied to the local set of devices.

5.6.1.3.2 GroupCmdReplyList command_inout (String c, boolean fwd)

Executes a Tango command on a group. This method is synchronous and does not return until replies are obtained or timeouts occurred.

The parameter c is the name of the command.

If fwd is set to true, the request is also forwarded to subgroups. Otherwise, it is only applied to the local set of devices.

Command results are returned in a GroupCmdReplyList. See Obtaining command results for details (4.6.3.1). See also Case I of Executing a command (4.6.3.2) for an example.
5.6.1.3.3 GroupCmdReplyList command_inout (String c, DeviceData d, boolean fwd)

Executes a Tango command on each device in the group. This method is synchronous and does not return until replies are obtained or timeouts occurred.

The parameter c is the name of the command.

The second parameter d is a Tango generic container for command carrying the command argument. See the Tango.DeviceData documentation.

If fwd is set to true, the request is also forwarded to subgroups. Otherwise, it is only applied to the local set of devices.

Command results are returned in a GroupCmdReplyList. See Obtaining command results for details (4.6.3.1). See also Case 2 of Executing a command (4.6.3.4) for an example.

5.6.1.3.4 DeviceData[] get_command_specific_argument_list (boolean fwd)

This helper method returns a "pre-build" argument list for commands executed with a specific argument for each device (see next method).

If fwd is set to true, the returned array’s length equals the number of devices in the local set. Otherwise, it equals the number of devices in the whole hierarchy.

The returned array can be kept and reused as far as the group structure is not changed (i.e. as far as no add/remove are executed on the group).

See Case 3 of Executing a command (4.6.3.5) for an example of this special form of command_inout.

5.6.1.3.5 GroupCmdReplyList command_inout (String c, DeviceData[] d, boolean fwd)

Executes a Tango command on each device in the group. This method is synchronous and does not return until replies are obtained or timeouts occurred.

This implementation of command_inout allows passing a specific input argument to each device in the group. In order to use this form of command_inout, the user must have an "a priori" and "perfect" knowledge of the devices order in the group.

The parameter c is the name of the command.

The array d contains a specific argument value for each device in the group. Its length must equal Group.get_size(fwd). Otherwise, an exception is thrown. The order of the argument values must follows the order of the devices in the group (d[0] => 1st device, d[1] => 2nd device and so on). A pre-build array of DeviceData can be obtained using Group.get_command_specific_argument_list.

If fwd is set to true, the request is also forwarded to subgroups. Otherwise, it is only applied to the local set of devices.

Command results are returned in a GroupCmdReplyList. See Obtaining command results for details (4.6.3.1). See also Case 3 of Executing a command (4.6.3.5) for an example of this special form of command_inout.

5.6.1.3.6 int command_inout_async (String c, boolean fgt, boolean fwd)

Executes a Tango command on each device in the group asynchronously. The method send the request to all devices and return immediately. Pass the returned request id to Group::command_inout_reply to obtain the results.

The parameter c is the name of the command.

The parameter fgt is a fire and forget flag. If set to true, it means that no reply is expected (i.e. the caller does not care about it and will not even try to get it).

If the parameter fwd is set to true request is forwarded to subgroups. Otherwise, it is only applied to the local set of devices.

See Case 1 of Executing a command (4.6.3.2) for an example.
5.6.1.3.7  int command_inout_async (String c, DeviceData d, boolean fgt, boolean fwd)

Executes a Tango command on each device in the group asynchronously. The method sends the request to all devices and returns immediately. Pass the returned request id to Group.command_inout_reply to obtain the results.

The parameter c is the name of the command.

The second parameter d is a Tango generic container for command carrying the command argument. See the TangoApi.DeviceData documentation for details.

The parameter fgt is a fire and forget flag. If set to true, it means that no reply is expected (i.e. the caller does not care about it and will not even try to get it).

If the parameter fwd is set to true request is forwarded to subgroups. Otherwise, it is only applied to the local set of devices.

See Case 2 of Executing a command for an example (4.6.3.4).

5.6.1.3.8  int command_inout_async (String c, DeviceData[] d, boolean fgt, boolean fwd)

Executes a Tango command on each device in the group asynchronously. The method sends the request to all devices and returns immediately. Pass the returned request id to Group.command_inout_reply() to obtain the results.

This implementation of command_inout allows passing a specific input argument to each device in the group. In order to use this form of command_inout_async, the user must have an "a priori" and "perfect" knowledge of the devices order in the group.

The parameter c is the name of the command.

The array d contains a specific argument value for each device in the group. Its length must equal Group.get_size(fwd). Otherwise, an exception is thrown. The order of the argument values must follows the order of the devices in the group (d[0] => 1st device, d[1] => 2nd device and so on). A pre-build array of DeviceData can be obtained using Group.get_command_specific_argument_list.

The parameter fgt is a fire and forget flag. If set to true, it means that no reply is expected (i.e. the caller does not care about it and will not even try to get it).

If fwd is set to true, the request is also forwarded to subgroups. Otherwise, it is only applied to the local set of devices.

See Case 3 of Executing a command (4.6.3.5) for an example of this special form of command_inout.

5.6.1.3.9  GroupCmdReplyList command_inout_reply (int req_id, int timeout_ms)

Returns the results of an asynchronous command.

The first parameter req_id is a request identifier previously returned by one of the command_inout_async methods.

For each device in the hierarchy, if the command result is not yet available, command_inout_reply will wait timeout_ms milliseconds before throwing an exception. This exception will be part of the global reply. If timeout_ms is set to 0, command_inout_reply waits "indefinitely".

Command results are returned in a GroupCmdReplyList. See Obtaining command results for details (4.6.3.1).

5.6.1.3.10  GroupAttrReplyList read_attribute (String a, boolean fwd)

Reads an attribute on each device in the group. This method is synchronous and does not return until replies are obtained or timeouts occurred.

The parameter a is the name of the attribute to read.

If fwd is set to true request is forwarded to subgroups. Otherwise, it is only applied to the local set of devices.
Attribute values are returned in a GroupAttrReplyList. See Obtaining attribute values for details (4.6.4.1). See also Reading an attribute for an example (4.6.4).

5.6.1.3.11 int read_attribute_asynch (String a, boolean fwd)
Reads an attribute on each device in the group asynchronously. The method send the request to all devices and return immediately. Pass the returned request id to Group.read_attribute_reply to obtain the results.

The parameter a is the name of the attribute to read.

If fwd is set to true request is forwarded to subgroups. Otherwise, it is only applied to the local set of devices.

See Reading an attribute for an example (4.6.4).

5.6.1.3.12 GroupAttrReplyList read_attribute_reply (int req_id, int timeout _ms)
Returns the results of an asynchronous attribute reading.

The first parameter req_id is a request identifier previously returned by read_attribute_asynch.

For each device in the hierarchy, if the attribute value is not yet available, read_attribute_reply wait timeout _ms milliseconds before throwing an exception. This exception will be part of the global reply. If timeout _ms is set to 0, read_attribute_reply waits "indefinitely".

Replies are returned in a GroupAttrReplyList. See Obtaining attribute values for details (4.6.4.1).

5.6.1.3.13 GroupReplyList write_attribute (DeviceAttribute d, boolean fwd)
Writes an attribute on each device in the group. This method is synchronous and does not return until acknowledgements are obtained or timeouts occurred.

The first parameter d is a Tango generic container for attribute carrying both the attribute name and the value. See the Tango.DeviceAttribute documentation for details.

If fwd is set to true request is forwarded to subgroups. Otherwise, it is only applied to the local set of devices.

Acknowledgements are returned in a GroupReplyList. See Obtaining acknowledgements for details (4.6.5.1). See also Case 1 of Writing an attribute for an example (4.6.5.2).

5.6.1.3.14 DeviceAttribute[] get_attribute_specific_value_list (boolean fwd)
This helper method returns a "pre-build" argument list for attribute writing executed with a specific argument for each device (see next method).

If fwd is set to true, the returned array’s length equals the number of devices in the local set. Otherwise, it equals the number of devices in the whole hierarchy.

The returned array can be kept and reused as far as the group structure is not changed (i.e. as far as no add/remove are executed on the group).

See also Case 2 of Writing an attribute for an example (4.6.5.3).

5.6.1.3.15 GroupReplyList write_attribute (String a, DeviceAttribute[] d, boolean fwd)
Writes an attribute on each device in the group. This method is synchronous and does not return until replies are obtained or timeouts occurred.

This implementation of write_attribute allows writing a specific value to each device in the group. In order to use this form of write_attribute, the user must have an "a priori" and "perfect" knowledge of the devices order in the group.

The parameter a is the name of the attribute.

The array d contains a specific value for each device in the group. Its size must equal Group.get_size(fwd). Otherwise, an exception is thrown. The order of the attribute values must
follows the order of the devices in the group (d[0] => 1st device, d[1] => 2nd device and so on). A pre-build array of DeviceAttribute can be obtained using Group.get_attribute_specific_value_list. If fwd is set to true request is forwarded to subgroups. Otherwise, it is only applied to the local set of devices.

Acknowledgements are returned in a GroupReplyList. See Obtaining acknowledgements for details (4.6.5.1). See also Case 2 of Writing an attribute for an example (4.6.5.3).

5.6.1.3.16 int write_attribute_async (DeviceAttribute d, boolean fwd)

Writes an attribute on each device in the group asynchronously. The method sends the request to all devices and returns immediately. Pass the returned request id to Group.write_attribute_reply() to obtain the acknowledgements.

The first parameter d is a Tango generic container for attribute carrying both the attribute name and the value. See the DeviceAttribute documentation for details.

If fwd is set to true request is forwarded to subgroups. Otherwise, it is only applied to the local set of devices.

See Case 1 of Writing an attribute for an example (4.6.5.2).

5.6.1.3.17 int write_attribute_async (String a, DeviceAttribute[] d, boolean fwd)

Writes an attribute on each device in the group asynchronously. The method send the request to all devices and return immediately. Pass the returned request id to Group.write_attribute_reply() to obtain the acknowledgements.

This implementation of write_attribute_async allows writing a specific value to each device in the group. Here, and contrary to the previous cases, the request is not and cannot be forwarded to sub-groups. Supporting such a feature introduces to much complexity for both the developer and the end user. In order to use this form of write_attribute_async, the user must have an "a priori" and "perfect" knowledge of the devices order in the group.

The parameter a is the name of the attribute.

The array d contains a specific value for each device in the group. Its size must equal Group.size(fwd). Otherwise, an exception is thrown. The order of the attribute values must follows the order of the devices in the group (d[0] => 1st device, d[1] => 2nd device and so on). A pre-build array of DeviceAttribute can be obtained using Group.get_attribute_specific_value_list.

If fwd is set to true request is forwarded to subgroups. Otherwise, it is only applied to the local set of devices.

See Case 2 of Writing an attribute for an example (4.6.5.3).

5.6.1.3.18 GroupReplyList write_attribute_reply (int req_id, int timeout_ms)

Returns the acknowledgements of an asynchronous attribute writing.

The first parameter req_id is a request identifier previously returned by one of the write_attribute_async implementation.

For each device in the hierarchy, if the acknowledgement is not yet available, write_attribute_reply wait timeout_ms milliseconds before throwing an exception. This exception will be part of the global reply. If timeout_ms is set to 0, write_attribute_reply waits "indefinitely".

Acknowledgements are returned in a GroupReplyList. See Obtaining acknowledgements for details (4.6.5.1).

5.7 Event related classes

5.7.1 TangoEventsAdapter class

This class is the main entry point for clients to subscribe as listeners of events coming from a given device. To instantiate an object of this class it is necessary to pass a DeviceProxy reference on
the related device to its constructor

5.7.1.0.19 Public void addTangoPeriodicListener(ITangoPeriodicListener listener, String attr_name, String[] filters)

Subscribes for a "periodic" event.

- Parameter listener : an object of a class implementing the ITangoPeriodicListener interface,
- Parameter attr_name : name of the attributes, the values of which will be pushed periodically to the listener object. The period will be fixed to the value of the event_period attribute's property otherwise it defaults to 1 second.
- Parameter filters : can be used to reduce the frequency at which periodic event is received. Not implemented in release 4.0.0

5.7.1.0.20 Public void removeTangoPeriodicListener(ITangoPeriodicListener listener, String attr_name)

Unsubscribes from a "periodic" event.

- Parameter listener : an object of a class implementing the ITangoPeriodicListener interface that was listening to the "periodic" event.
- Parameter attr_name : name of the attribute for which the subscription was made.

5.7.1.0.21 Public void addTangoChangeListener(ITangoChangeListener listener, String attr_name, String[] filters)

Subscribes for a "change" event.

- Parameter listener : an object of a class implementing the ITangoChangeListener interface
- Parameter attr_name : name of the attributes, the values of which will be pushed if they have changed relatively or absolutely depending on the "rel_change" and "abs_change" attribute's property values.
- Parameter filters : can be specified to filter events on relative change or absolute change. Not implemented in release 4.0.0

5.7.1.0.22 Public void removeTangoChangeListener(ITangoChangeListener listener, String attr_name)

Unsubscribes from a "change" event.

- Parameter listener : an object of a class implementing the ITangoChangeListener interface that was listening to the "change" event
- Parameter attr_name : name of the attribute for which the subscription was made.

5.7.1.0.23 Public void addTangoQualityChangeListener(ITangoQualityChangeListener listener, String attr_name)

Subscribes for a "quality_change" event.

- Parameter listener : an object of a class implementing the ITangoQualityChangeListener interface.
• Parameter `attr_name` : name of the attributes, the quality factor changes (from valid to alarm or vice versa) of which will be sent to the listener object.

• Parameter `filters` : filters if any. Not implemented in release 4.0.0

5.7.1.0.24 Public void removeTangoQualityChangeListener(ITangoQualityChangeListener listener, String `attr_name`)

Unsubsribes from a "quality_change" event.

• Parameter `listener` : an object of a class implementing the `ITangoQualityChangeListener` interface that was listening to the "quality_change" event.

• Parameter `attr_name` : name of the attribute for which the subscription was made.

5.7.1.0.25 1.3.1.7 Public void addTangoArchiveListener(ITangoArchiveListener listener, String `attr_name`, String[] `filters`)

Subscribes for an "archive" event.

• Parameter `listener` : an object of a class implementing the `ITangoArchiveListener` interface.

• Parameter `attr_name` : name of the attributes, the values of which will be pushed to the listener object based on a mixture of conditions defined by the attribute's properties : `archive_rel_change`, `archive_abs_change` and `archive_period`.

• Parameter `filters` : can be specified to define the mixture of archiving related attribute's properties. No timplemented in Release 4.0.0

5.7.1.0.26 Public void removeTangoArchiveListener(ITangoArchiveListener listener, String `attr_name`, String[] `filters`)

Unsubsribes from a "archive" event.

• Parameter `listener` : an object of a class implementing the `ITangoArchiveListener` interface that was listening to the "periodic" event.

• Parameter `attr_name` : name of the attribute for which the subscription was made.

5.7.2 `ITangoPeriodicListener` interface

When a client subscribes for a periodic event, it passes to the `TangoEventsAdapter` an object reference on a class implementing the `ITangoPeriodicListener` interface that declares only one method.

5.7.2.0.27 public void periodic(TangoPeriodicEvent `evt`)

This method is called by the event source each time a new period has elapsed.

• Parameter `evt` : a TangoPeriodicEvent holding all necessary information

5.7.3 `ITangoChangeListener` interface

When a client subscribes for a change event, it passes to the `TangoEventsAdapter` an object reference on a class implementing the `ITangoChangeListener` interface that declares only one method.
5.7.3.0.28 public void change(TangoChangeEvent evt)
This method is called by the event source each time the value of the attribute associated to the event has changed

- Parameter evt : a TangoChangeEvent holding all necessary information

5.7.4 ITangoQualityChangeListener interface
When a client subscribes for a quality_change event, it passes to the TangoEventsAdapter an object reference on a class implementing the ITangoQualityChangeListener interface that declares only one method.

5.7.4.0.29 public void qualityChange(TangoQualityChangeEvent evt)
This method is called by the event source each time the attribute’s value quality associated to the event has changed (from valid to alarm) or vice versa.

- Parameter evt : a TangoQualityChangeEvent holding all necessary information

5.7.5 ITangoArchiveListener interface
When a client subscribes for an archive event, it passes to the TangoEventsAdapter an object reference on a class implementing the ITangoArchiveListener interface that declares only one method.

5.7.5.0.30 public void archive(TangoArchiveEvent evt)
This method is called by the event source each time a new attribute’s data is ready to be archived based on the archiving modes chosen for this attribute.

- Parameter evt : a TangoArchiveEvent holding all necessary information

5.7.6 TangoPeriodicEvent class
This class represents data objects associated with a periodic event. To get the attribute’s related data, the following method has to be called.

5.7.6.0.31 public DeviceAttribute getValue()
Returns value of the attribute associated to the event

5.7.7 TangoChangeEvent class
This class represents data objects associated with a change event. To get the attribute’s related data, the following method has to be called.

5.7.7.0.32 public DeviceAttribute getValue()
Returns value of the attribute associated to the event

5.7.8 TangoQualityChangeEvent class
This class represents data objects associated with a quality_change event. To get the attribute’s related data, the following method has to be called.
5.7.8.0.33 public DeviceAttribute getValue()
Returns value of the attribute associated to the event

5.7.9 TangoArchiveEvent class
This class represents data objects associated with an archive event. To get the attribute’s related data, the following method has to be called.

5.7.9.0.34 public DeviceAttribute getValue()
Returns value of the attribute associated to the event

5.8 Database access classes

5.8.1 Database class
5.8.1.1 General information methods
5.8.1.1.1 Creating a Database object
Do NOT use a Database constructor.
To manage an single connection an a host database, the Database object must be created through the ApiUtil class.

```
Database dbase = ApiUtil.get_db_obj();
```

5.8.1.1.2 String get_info()
Query the database for general info about the table in the database.
- Return the result of the query as String.

```
Database dbase = ApiUtil.get_db_obj();
String info = dbase.get_info();
System.out.println(info);
```

5.8.1.1.3 String[] get_host_list()
Query the database for a list of host registered.
- Return the list of all hosts registered in TANGO database.

5.8.1.1.4 String[] get_host_list(String wildcard)
Query the database for a list of host registered.
- parameter wildcard : filter (* matches any character e.g. a*)
- Return the list of the hosts registered in TANGO database with the specified wildcard.
5.8.1.1.5  String[] get_server_list()
Query the database for a list of servers registered in the database.

- Return the list of all servers registered in TANGO database.

5.8.1.1.6  String[] get_server_list(String wildcard)
Query the database for a list of servers registered in the database.

- parameter wildcard: filter (*) matches any character e.g. a*).
- Return the list of all servers registered in TANGO database.

5.8.1.1.7  String[] get_host_server_list(String hostname)
Query the database for a list of servers registered on the specified host.

- parameter hostname: the specified host name.
- Return the list of the servers registered in TANGO database for the specified host.

5.8.1.1.8  String[] get_server_class_list(String servname)
Query the database for a list of classes instanced by the server. The DServer class exists in all
TANGO servers and for this reason this class is removed of the returned list.

- parameter servname: the specified server and its instance name (e.g. Serial/1).
- Return The list of classes instanced by this server.

5.8.1.1.9  void put_server_info(DbServInfo info)
Add/update server information in database.

- parameter info: Server information for the specified server
- in a DbServInfo object.

```java
String[] hosts = get_host_list("amber*");
for (int i=0 ; i<hosts.length ; i++)
    System.out.println(hosts[i]);

String[] servers = get_host_server_list("corvus");
for (int i=0 ; i<servers.length ; i++)
    System.out.println(servers[i]);
```

```java
DbServerInfo  info = new DbServerInfo("Serial/linel");
info.host = corvus;  // Will be registered on
info.controlled = true;  // Will be controlled by Astor
info.startup_level = 4;  // Startup level used by Astor.
put_server_info(info);
```
5.8.1.1.10 **DbServInfo get_server_info(String servname)**
Query the database for server information.
- **parameter servname**: The specified server name.

- **Return**: The information found for the specified server in a DBServInfo object.

5.8.1.2 **Object property methods**

5.8.1.2.1 **DbDatum[] get_property(String name, String[] propnames)**
Query the database for a list of object (i.e. non-device) properties for the specified object.
- **parameter name**: Object name.
- **parameter propnames**: list of property names.

```
String[] propnames = {"Speed", "Temperatures"};
DbDatum[] prop = dbase.get_property("my_object", data);
if (prop[0].is_empty()==false)
    System.out.println(prop[0].name + " : " + prop[0].extractDouble());
if (prop[1].is_empty()==false)
    System.out.println(prop[1].name + " : " + prop[1].extractFloat());
```

5.8.1.2.2 **DbDatum get_property(String name, String propname)**
Query the database for an object (i.e. non-device) property for the specified object.
- **parameter name**: Object name.
- **parameter propname**: list of property names.

```
DbDatum prop = dbase.get_property("my_object", "Speed");
if (prop.is_empty()==false)
    System.out.println(prop.name + " : " + prop.extractDouble());
```

5.8.1.2.3 **DbDatum[] get_property(String name, DbDatum[] properties)**
Query the database for a list of object (i.e. non-device) properties for the specified object. The property names are specified by the DbDatum array objects.
- **parameter name**: Object name.
- **parameter properties**: list of property DbDatum objects.

```
```
DbDatum[] datum;
datum = new DbDatum[2];
datum[0] = new DbDatum(“Speed”);
datum[1] = new DbDatum(“Temperature”);
DbDatum[] prop = dbase.get_property(“my_object”, data);

if (prop[0].is_empty()==false)
    System.out.println(prop[0].name + “: “ + prop[0].extractDouble());
if (prop[1].is_empty()==false)
    System.out.println(prop[1].name + “: “ + prop[1].extractFloat());

5.8.1.2.4 void put_property(String name, DbDatum[] properties)
Insert or update a list of properties for the specified object. The property names and their values
are specified by the DbDatum array.

- parameter name : Object name.
- parameter properties : Properties names and values array.

DbDatum[] datum;
datum = new DbDatum[2];
datum[0] = new DbDatum(“Speed”, 123.456);
datum[1] = new DbDatum(“Temperature”, 21.5);
dbase.put_property(“my_object”, data);

5.8.1.2.5 void delete_property(String name, String[] propnames)
Delete a list of properties for the specified object.

- parameter name : Object name.
- parameter propnames : Property names.

5.8.1.2.6 void delete_property(String name, String propname)
Delete a property for the specified object.

- parameter name : Object name.
- parameter propname : Property names.

5.8.1.2.7 void delete_property(String name, DbDatum[] properties)
Delete a list of properties for the specified object.

- parameter name : Object name.
- parameter properties : Property DbDatum objects.
5.8.1.3 Device Methods

5.8.1.3.1 void add_device(DbDevInfo devinfo)
Add/update a device to the database

- parameter devinfo: The device name, class and server specified in object.

```java
DbDevInfo devinfo =
    new DbDevInfo("sys/database/1", "Dbase", "Database/1");
dbase.add_device(devinfo);
```

5.8.1.3.2 void delete_device(String devname)
Delete the device of the specified name from the database

- parameter devname: The device name.

5.8.1.3.3 DbDevImportInfo import_device(String devname)
Query the database for the export info of the specified device.

- parameter devname: The device name.
- Return the information in a DbDevImportInfo.

```java
DbDevImportInfo info = dbase.import_device(devname);
String name      = info.name;
String ior       = info.iort;   // IOR connection as String.
String version   = info.version; // TANGO protocol version number.
boolean exp      = info.exported; // true if device is exported.
```

5.8.1.3.4 void unexport_device(String servname)
Mark the specified server as unexported in the database.

- parameter servname: The server name.

5.8.1.3.5 void export_device(DbDevExportInfo devinfo)
Update the export info for this device in the database.

- parameter devinfo: Device information to export.

```java
DbDevExportInfo exp_info =
    new DbDevExportInfo(devname, "Serial/line1", imp_info.iort,
                        "corvus", imp_info.version);
dbase.export_device(exp_info);
```
5.8.1.3.6 String[] get_device_class_list(String servname)
Query the database for a list of devices and classes served by the specified server.
- parameter servname: The server name.
- Return the device names are stored in an array of strings.

5.8.1.3.7 String[] get_device_name(String servname, String classname)
Query the database for a list of devices served by the specified server and of the specified class.
- parameter servname: The server name.
- parameter classname: The class name
- Return the device names are stored in an array of strings.

    String[] names = dbase.get_device_name("Serial/line1", "Serial");

5.8.1.3.8 String[] get_device_domain(String wildcard)
Query the database for a list of device domain names which match the wildcard provided.
- parameter wildcard: filter (* matches any character e.g. a*).
- Return the device domain are stored in an array of strings.

    String[] domains = get_device_domain("sy*");

5.8.1.3.9 String[] get_device_family(String wildcard)
Query the database for a list of device family names which match the wildcard provided.
- parameter wildcard: filter (* matches any character e.g. a*).
- Return the device family are stored in an array of strings.

    String[] families = get_device_family("sys/*data*");

5.8.1.3.10 String[] get_device_member(String wildcard)
Query the database for a list of device member names which match the wildcard provided.
- parameter wildcard: filter (* matches any character e.g. a*).
- Return the device member are stored in an array of strings.

    String[] members = get_device_member("sys/database/*");
5.8.1.4 Device property methods

5.8.1.4.1 String[] get_device_property_list(String devname, String wildcard)
Query the database for a list of device properties for the specified object.

- parameter devname : name of the specified device.
- parameter wildcard : filter (* matches any character e.g. a*)
- Return the property names in a String array.

5.8.1.4.2 DbDatum[] get_device_property(String name, String[] pronames)
Query the database for a list of device properties for the specified object.

- parameter name : device name.
- parameter pronames : list of property names.
- Return properties in DbDatum objects.

```java
String[] pronames = {"Speed", "Temperatures"};
DbDatum[] prop = dbase.get_property("sys/motor/1", pronames);

if (prop[0].is_empty() == false)
    System.out.println(prop[0].name + " : " + prop[0].extractDouble());
if (prop[1].is_empty() == false)
    System.out.println(prop[1].name + " : " + prop[1].extractFloat());
```

5.8.1.4.3 DbDatum get_device_property(String name, String proname)
Query the database for a device property for the specified object.

- parameter name : device name.
- parameter proname : property name.
- Return property in DbDatum object.

```java
DbDatum prop = dbase.get_property("sys/motor/1", "Speed");
if (prop.is_empty() == false)
    System.out.println(prop.name + " : " + prop.extractDouble());
```

5.8.1.4.4 DbDatum[] get_device_property(String name, DbDatum[] properties)
Query the database for a list of device properties for the specified object. The property names are specified by the DbDatum array objects.

- parameter name : device name.
• parameter properties : list of property DbDatum objects.

```
DbDatum[] datum;
datum = new DbDatum[2];
datum[0] = new DbDatum(“speed”);
datum[1] = new DbDatum(“temperature”);
DbDatum[] prop = dbase.get_property(“sys/motor/1”, datum);
if (prop[0].is_empty()==false)
    System.out.println(prop[0].name + “: “ + prop[0].extractDouble());
if (prop[1].is_empty()==false)
    System.out.println(prop[1].name + “: “ + prop[1].extractFloat());
```

5.8.1.4.5 void put_device_property(String name, DbDatum[] properties)

Insert or update a list of properties for the specified device. The property names and their values are specified by the DbDatum array.

• parameter name : device name.

• parameter properties : Properties names and values array.

```
DbDatum[] datum;
datum = new DbDatum[2];
datum[0] = new DbDatum(“speed”, 123.456);
datum[1] = new DbDatum(“temperature”, 21.5);
dbase.put_property(“sys/motor/1”, datum);
```

5.8.1.4.6 void delete_device_property(String name, String[] propnames)

Delete a list of properties for the specified object.

• parameter name : Device name.

• parameter propnames : Property names.

5.8.1.4.7 void delete_device_property(String name, String propname)

Delete a property for the specified object.

• parameter name : Device name.

• parameter propname : Property name.

5.8.1.4.8 void delete_device_property(String name, DbDatum[] properties)

Delete a list of properties for the specified object.

• parameter name : Device name.

• parameter properties : Property DbDatum objects.
5.8.1.5 Device attribute methods

5.8.1.5.1 String[] get_device_attribute_list(String devname, String wildcard)
Query the database for a list of attribute names for the specified object.

- parameter devname: device name.
- parameter wildcard: filter (* matches any character e.g. a*).
- Return attribute names found in a String array.

5.8.1.5.2 DbAttribute[] get_device_attribute_property(String name, String[] atnames)
Query the database for a list of device attribute properties for the specified object.

- parameter name: Device name.
- parameter atnames: list of attribute names.
- Return properties in DbAttribute array.

```java
String devname = "sys/serial/1";
String[] atnames = db.get_device_attribute_list(devname, "*");
DbAttribute[] attr = db.get_device_attribute_property(devname, atnames);
for (int i=0; i<attr.length; i++)
    for (int j=0; j<attr[i].size(); j++)
    {
        DbDatum datum = attr[i].datum(j);
        System.out.println(datum.name + "\t" + datum.extractString());
    }
```

5.8.1.5.3 DbAttribute get_device_attribute_property(String name, String atname)
Query the database for a list of device attribute properties for the specified objects.

- parameter name: device name.
- parameter atname: attribute name.
- Return properties in DbAttribute array.
5.8.1.5.4 void put_device_attribute_property(String name, DbAttribute[] attr)
Insert or update a list of attribute properties for the specified device. The property names and their values are specified by the DbAttribute array.

- parameter name : device name.
- parameter attr : attribute names and properties (names and values) array.

```
DbAttribute[] attr = new DbAttribute[2];
// Set Second attribute properties
                    attr[0] = new DbAttribute("Temperature");
attr[0].add("Unit", "Kelvin");
attr[0].add("Format", "fixed;showpos;setprecision(1)");
attr[0].add("Label", "Temperature read");
// Set Second attribute properties
                    attr[1] = new DbAttribute("Current");
attr[1].add("Unit", "Amp.");
attr[1].add("Format", "fixed;setprecision(3)");
attr[1].add("Label", "Dipole Current Read");
// Put property in database
                    db.put_device_attribute_property(devname, attr);
```

5.8.1.5.5 void put_device_attribute_property(String name, DbAttribute[] attr)
Insert or update a list of attribute properties for the specified device. The property names and their values are specified by the DbAttribute array.

- parameter name : device name.
- parameter attr : attribute names and properties (names and values).

5.8.1.5.6 void delete_device_attribute_property(String name, String[] propnames)
Delete a list of properties for the specified object.

- parameter name : Device name.
- parameter propnames : Property names.

5.8.1.5.7 void delete_device_attribute_property(String name, String propname)
Delete a property for the specified object.

- parameter name : Device name.
- parameter propname : Property name.

5.8.1.5.8 void delete_device_attribute_property(String name, DbAttribute[] attr)
Delete a list of properties for the specified object.

- parameter name : Device name.
- parameter attr : attribute names and properties (names and values).
5.8.1.5.9 void delete_device_attribute_property(String name, DbAttribute attr)
Delete a list of properties for the specified object.

- parameter name: Device name.
- parameter attr: attribute name and properties (names and values).

5.8.1.5.10 void delete_device_attribute(String devname, String attname)
Delete an attribute for a device.

- parameter devname: Device name.
- parameter attname: Attribute name.

5.8.1.6 Server methods
5.8.1.6.1 void add_server(String servname, DbDevInfo[] devinfos)
Add a group of devices to the database.

- parameter servname: Server name for these devices.
- parameter devinfo: Devices and server information.

```java
DbDevInfo[] devinfos;
devinfos = new DbDevInfo[2];
devinfos[0] = new DbDevInfo("sys/dummy/check3", "Dummy", "Dummy/check3");
devinfos[1] = new DbDevInfo("sys/dummy/check4", "Dummy", "Dummy/check3");
dbase.add_server(devinfos[0].name, devinfos);
```

5.8.1.6.2 void delete_server(String servname)
Delete the device server and its associated devices from the database.

- parameter servname: the server name.

5.8.1.6.3 void export_server(DbDevExportInfo[] devinfos)
Export a group of devices to the database. The device name, IOR, servname etc are specified in the DbDevExportInfo array.

- parameter servname: server name for these devices.
- parameter devinfo: Devices and server information.

5.8.1.6.4 void unexport_server(String devname)
Mark all devices exported for this device server as unexported.

- parameter devname: the device name.
5.8.1.7 Class property methods

5.8.1.7.1 String[] get_class_property_list(String classname, String wildcard)
Query the database for a list of class properties for the specified object.

- parameter classname: name of the specified class.
- parameter wildcard: filter (* matches any character e.g. a*).
- Return the property names in a String array.

5.8.1.7.2 DbDatum[] get_class_property(String name, String[] pronames)
Query the database for a list of class properties for the specified object.

- parameter name: Class name.
- parameter pronames: list of property names.
- Return properties in DbDatum objects.

5.8.1.7.3 DbDatum get_class_property(String name, String proname)
Query the database for a class property for the specified object.

- parameter name: Class name.
- parameter proname: list of property names.
- Return property in DbDatum object.

5.8.1.7.4 DbDatum[] get_class_property(String name, DbDatum[] properties)
Query the database for a list of class properties for the specified object. The property names are specified by the DbDatum array objects.

- parameter name: Class name.
- parameter properties: list of property DbDatum objects.
- Return properties in DbDatum objects.

5.8.1.7.5 void put_class_property(String name, DbDatum[] properties)
Insert or update a list of properties for the specified class. The property names and their values are specified by the DbDatum array.

- parameter name: Class name.
- parameter properties: Properties names and values array.

5.8.1.7.6 void delete_class_property(String name, String[] pronames)
Delete a list of properties for the specified object.

- parameter name: Class name.
- parameter pronames: Property names.
5.8.1.7.7  void delete_class_property(String name, String propname)
Delete a property for the specified object.
   • parameter name : Class name.
   • parameter propname : Property name.

5.8.1.7.8  void delete_class_property(String name, DbDatum[] properties)
Delete a list of properties for the specified object.
   • parameter name : Class name.
   • parameter properties : Property DbDatum objects.

5.8.1.8   Class attribute Methods
5.8.1.8.1  String[] get_class_attribute_list(String classname, String wildcard)
Query the database for a list of attribute names for the specified object.
   • parameter classname : class name.
   • parameter wildcard : filter (* matches any character e.g. a*).
   • Return attribute names found in a String array.

5.8.1.8.2  DbAttribute[] get_class_attribute_property(String name, String[] attnames)
Query the database for a list of class attribute properties for the specified object.
   • parameter name : Class name.
   • parameter propnames : list of attribute names.
   • Return properties in DbAttribute array.

    String[] attnames = db.get_class_attribute_list("MyClass", "");
    DbAttribute[] attr = db.get_class_attribute_property("MyClass", attnames);
    for (int i=0 ; i<attr.length ; i++)
     for (int j=0 ; j<att[i].getSize() ; j++)
      {
       DbDatum datum = att[i].datum(j);
       System.out.println(datum.name + ":\t" + datum.extractString());
      }
    //
    // ========= Or ===========
    //
    String propname = "Label";
    String[] attnames = db.get_class_attribute_list("MyClass", "");
    DbAttribute[] attr = db.get_class_attribute_property("MyClass", attnames);
    String _label = "Default string";
    if (attr[i].is_empty(propname)==false)
     label = attr[i].get_value(propname);
5.8.1.8.3 DbAttribute get_class_attribute_property(String name, String attname)
Query the database for a list of class attribute properties for the specified objects.
   • parameter name : Class name.
   • parameter propname : attribute name.
   • Return properties in DbAttribute object.

5.8.1.8.4 void put_class_attribute_property(String name, DbAttribute[] attr)
Insert or update a list of attribute properties for the specified class. The property names and their
values are specified by the DbAttribute array.
   • parameter name : Class name.
   • parameter attr : attribute names and properties (names and values) array.

```
DbAttribute[] attr = new DbAttribute[2];
// Set Second attribute properties
// -----------------------------------------------
attr[0] = new DbAttribute("Temperature");
attr[0].add("Unit", "Kelvin");
attr[0].add("Format", "fixed;showpos;setprecision(1)" );
attr[0].add("Label", "Temperature read");
// Set Second attribute properties
// -----------------------------------------------
attr[1] = new DbAttribute("Current");
attr[1].add("Unit", "Amp.");
attr[1].add("Format", "fixed;setprecision(3)" );
attr[1].add("Label", "Dipole Current Read");
// Put property in database
// -----------------------------------------------
db.put_class_attribute_property("MyClass", attr);
```

5.8.1.8.5 void put_class_attribute_property(String name, DbAttribute attr)
Insert or update a list of attribute properties for the specified class. The property names and their
values are specified by the DbAttribute array.
   • parameter name : Class name.
   • parameter attr : attribute name and properties (names and values) array.

5.8.1.8.6 void delete_class_attribute_property(String name, String[] propnames)
Delete a list of properties for the specified object.
   • parameter name : Class name.
   • parameter propnames : Property names.
5.8.1.8.7  void delete_class_attribute_property(String name, String propname)
Delete a property for the specified object.
  
  - parameter name : Class name.
  - parameter propname : Property names.

5.8.1.8.8  void delete_class_attribute_property(String name, DbDatum[] properties)
Delete a list of properties for the specified object.
  
  - parameter name : Class name.
  - parameter properties : Property DbDatum objects.

5.8.2  DbClass class
5.8.2.1  Class property methods
5.8.2.1.1  DbClass(String classname)
Database object used for TANGO database access.

5.8.2.1.2  String[] get_property_list(String wildcard)
Query the database for a list of class properties for this class.
  
  - parameter wildcard : filter (* matches any character e.g. a*).
  - Return the property names in a String array.

5.8.2.1.3  DbDatum[] get_property(String[] propnames)
Query the database for a list of properties for this class.
  
  - parameter propnames : list of property names.
  - Return properties in DbDatum objects.

5.8.2.1.4  DbDatum get_property(String propnames)
Query the database for a property for this class.
  
  - parameter propname : property name.
  - Return properties in DbDatum object.

5.8.2.1.5  DbDatum[] get_property(DbDatum[] properties)
Query the database for a list of properties for this class. The property names are specified by the
DbDatum array objects.
  
  - parameter properties : list of property DbDatum objects.
  - Return properties in DbDatum objects.
5.8.2.1.6 void put_property(DbDatum[] properties)
Insert or update a list of properties for this class. The property names and their values are specified by the DbDatum array.
- parameter properties: Properties names and values array.

5.8.2.1.7 void delete_property(String[] pronames)
Delete a list of properties for this class.
- parameter pronames: Property names.

5.8.2.1.8 void delete_property(String propname)
Delete a property for this class.
- parameter propname: Property name.

5.8.2.1.9 void delete_property(DbDatum[] properties)
Delete a list of properties for this class.
- parameter properties: Property DbDatum objects.

5.8.2.2 Class attribute methods
5.8.2.2.1 String[] get_attribute_list(String wildcard)
Query the database for a list of attribute names for the specified object.
- parameter wildcard: filter (* matches any character e.g. a*).
  - Return attribute names found in a String array.

5.8.2.2.2 void put_attribute_property( DbAttribute attr)
Insert or update a list of attribute properties for this class. The property names and their values are specified by the DbAttribute array.
- parameter attr: Attribute names and properties (names and values).

5.8.2.2.3 void put_attribute_property( DbAttribute attr)
Insert or update a list of attribute properties for this class. The property names and their values are specified by the DbAttribute array.
- parameter attr: Attribute names and properties (names and values).

5.8.2.2.4 void delete_attribute_property(String[] pronames)
Delete a list of properties for this object.
- parameter pronames: Property names.

5.8.2.2.5 delete_attribute_property(String propname)
Delete a property for this object.
- parameter propname: Property name.
5.8.2.2.6 delete_attribute_property(DbDatum[] properties)
Delete a list of properties for this object.

- parameter properties : Property DbDatum objects.

5.8.2.2.7 DbDatum[] get_attribute_property(String[] propnames)
Query the database for a list of class attribute properties for this device.

- parameter propnames : list of property names.
- Return properties in DbDatum objects.

5.8.2.2.8 DbAttribute[] get_attribute_property(String[] attnames)
Query the database for a list of class attribute properties for the specified object.

- parameter propnames : list of attribute names.
- Return properties in DbAttribute array.

```java
DbClass myclass = new DbClass("MyClass");
String[] attnames = myclass.get_property_list("*");
DbAttribute[] attr = myclass.get_attribute_property(attnames);
for (int i=0 ; i<attr.length ; i++)
    for (int j=0 ; j<attr[i].size() ; j++)
    {
        DbDatum datum = attr[i].datum(j);
        System.out.print(datum.name + ";" + datum.extractString());
    }
```

5.8.2.2.9 DbAttribute get_attribute_property(String propname)
Query the database for a class attribute property for this object.

- parameter propname : property name.
- Return property in DbAttribute objects.

5.8.2.2.10 DbDatum[] get_attribute_property(DbDatum[] properties)
Query the database for a list of class attribute properties for this device. The property names are specified by the DbDatum array objects.

- parameter properties : list of property DbDatum objects.
- Return properties in DbDatum objects.

5.8.2.3 General information methods
5.8.2.3.1 String name()
This method does not throw any exception.

- return the class name.
5.8.2.4 Device aliases related methods

5.8.2.4.1 public String[] get_device_alias_list(String wildcard)
Query the database for a list of aliases for the specified wildcard.
- parameter wildcard : Wildcard char is '*' and matches wildcard characters.
- return the device aliases are stored in an array of strings.

5.8.2.4.2 String[] get_device_alias(String devname)
Query the database for a list of aliases for the specified device.
- parameter devname : The server name.
- Return the device aliases are stored in an array of strings.

5.8.2.4.3 public String get_alias_device(String alias)
Query the database a device for the specified alias.
- parameter alias: alias name to query device name.
- returns the device name for specified alias.

5.8.2.4.4 public void put_device_alias(String devname, String aliasname)
Set an alias for a device name.
- parameter devname: device name.
- parameter aliasname: alias name.

5.8.2.4.5 public void delete_device_alias(String alias)
Query the database to delete alias for the specified device alias.
- parameter alias: device alias name.

5.8.2.5 Device aliases related methods.

5.8.2.5.1 String[] get_attribute_alias_list(String wildcard)
Query the database for a list of aliases for the specified wildcard.
- parameter wildcard: Wildcard char is '*' and matches wildcard characters.
- return the device aliases are stored in an array of strings.

5.8.2.5.2 public String get_attribute_alias(String atname)
Query the database for a list of aliases for the specified attribute.
- parameter devname: The server name.
- return the device aliases are stored in an array of strings.
5.8.2.5.3 `public void put_attribute_alias(String attname, String aliasname)`
Set an alias for a attribute name.
- parameter attname: attribute name.
- parameter aliasname: alias name.

5.8.2.5.4 `public void delete_attribute_alias(String alias)`
Query the database to delete alias for the specified attribute alias.
- parameter alias: device alias name.

5.8.3 DbServer class
This class manage database connection for Tango server.

5.8.3.0.5 `public DbServer(String servname)`
DbServer constructor. It makes a connection to the TANGO database for server management.
- Parameter servname : Name of the class object.

5.8.3.0.6 `public DbServer(String servname, Database dbase)`
DbServer constructor. It makes a connection to the TANGO database for server management.
- Parameter servname : Name of the class object.
- Parameter dbase : Database object previously created.

5.8.3.0.7 `String[] get_class_list()`
Query the database for a list of classes instanced by this server. The DServer class exists in all TANGO servers and for this reason this class is removed of the returned list.
- Return The list of classes instanced by this server.

5.8.3.0.8 `public DbServInfo get_info()`
Query the database for server information.
- Return The information found for this server in a DbServInfo object.

```java
DbServer server = new DbServer(“Serial/line1”);
DbServInfo info = server.get_info();
System.out.println(“Server name: “ + server.name);
System.out.println(“Registered on: “ + server.host);
if (server.controlled)
    System.out.println(“Auto Start level: “ + server.startup_level);
```
5.8.3.0.9  public void put_info(DbServInfo info) throws DevFailed
Add/update server information in database.
  • Parameter info : Server information for this server in a DbServInfo object.

5.8.3.0.10  String[] get_device_class_list()
Query the database for a list of devices and classes served by this server.
  • Return the device names are stored in an array of strings.

5.8.3.0.11  String[] get_device_name(String classname)
Query the database for a list of devices served by this server, for the specified class.
  • parameter classname : The class name
  • Return the device names are stored in an array of strings.

  String[] names = server.get_device_name(“Serial”);

5.8.3.0.12  public String name()
This method does not throw any exception.
  • return the server name.
Chapter 6

The TANGO C++ Application Programmer Interface

6.1 Tango::DeviceProxy()

The high level object which provides the client with an easy-to-use interface to TANGO devices. DeviceProxy is a handle to the real Device (hence the name Proxy) and is not the real Device (of course). DeviceProxy provides interfaces to all TANGO Device interfaces. The DeviceProxy manages timeouts, stateless connections (new DeviceProxy() nearly always works), and reconnection if the device server is restarted.

6.1.1 Constructors

6.1.1.1 DeviceProxy::DeviceProxy(string &name, CORBA::ORB *orb= NULL)

Create a DeviceProxy to a device of the specified name. The TANGO HOST environment variable is used to determine which TANGO database to connect to. The client can specify an ORB as argument if she wants to. The constructor will connect to the TANGO database, query for the client’s network address and build a connection to the device. If the device is defined in the TANGO database but the device server is not running DeviceProxy will try to build a connection every time the client tries to access the device. If the device is not defined an exception is thrown. Example:

```cpp
DeviceProxy *my_device = new DeviceProxy("my/own/device");
```

See appendix on device naming for all details about Tango device naming syntax. If an alias name is defined for the device, this alias name can be used to create the DeviceProxy instance. Exception: WrongNameSyntax, ConnectionFailed

6.1.1.2 DeviceProxy::DeviceProxy(const char *name, CORBA::ORB *orb = NULL)

Idem previous call

6.1.2 Miscellaneous methods

6.1.2.1 DeviceInfo DeviceProxy::info()

A method which returns information on the device in a DeviceInfo structure. Example:
cout << "device info : " << endl
DeviceInfo dev_info = my_device->info() << endl;
cout << " dev_class " << dev_info.dev_class;
cout << " server_id " << dev_info.server_id;
cout << " server_host " << dev_info.server_host;
cout << " server_version " << dev_info.server_version;
cout << " doc_url " << dev_info.doc_url;
cout << " device_type " << dev_info.dev_type;

All DevInfo fields are strings except for the server_version which is a long integer.  
Exception: Connection Failed, CommunicationFailed, DevFailed from device

6.1.2.2 DevState DeviceProxy::state()
A method which return the state of the device as a Tango::DevState type. Example:

dev_state = my_device->state() << endl;

Exception: ConnectionFailed, CommunicationFailed

6.1.2.3 string DeviceProxy::status()
A method which return the status of the device as a string. Example:

cout << "device status " << my_device->status() << endl;

Exception: ConnectionFailed, CommunicationFailed

6.1.2.4 int DeviceProxy::ping()
A method which sends a ping to the device and returns the time elapsed as microseconds. Example:

cout << " device ping took " << my_device->ping() << " microseconds" << endl;

Exception: ConnectionFailed, CommunicationFailed

6.1.2.5 void DeviceProxy::set_timeout_millis(int timeout)
Set client side timeout for device in milliseconds. Any method which takes longer than this time to execute will throw an exception.

Exception: none
6.1.2.6 int DeviceProxy::get_timeout_millis()

Get the client side timeout in milliseconds.

*Exception: none*

6.1.2.7 int DeviceProxy::get_idl_version()

Get the version of the Tango Device IDL interface implemented by the device

*Exception: none*

6.1.2.8 void DeviceProxy::set_source(DevSource source)

Set the data source (device, polling buffer, polling buffer than device) for command_inout and read_attribute methods. The DevSource is an enumerated type which can be one of \{DEV, CACHE, CACHE_DEV\}. The default value is CACHE_DEV. See chapter on Advanced Feature for all details regarding polling.

*Exception: none*

6.1.2.9 DevSource DeviceProxy::get_source()

Get the device data source used by command_inout or read_attribute methods. The DevSource is an enumerated type which can be one of \{DEV, CACHE, CACHE_DEV\}. See chapter on Advanced Feature for all details regarding polling.

*Exception: none*

6.1.2.10 vector<string> *DeviceProxy::black_box(int n)

Get the last n commands executed on the device server and return a pointer to a vector of strings containing the date, time, command, and from which client computer the command was executed. This method allocates memory for the vector of strings returned to the caller. It is the caller responsibility to delete this memory.

*Exception: ConnectionFailed, CommunicationFailed, DevFailed from device*

6.1.2.11 string DeviceProxy::name()

Return the device name (from the device itself)

*Exception: ConnectionFailed, CommunicationFailed*

6.1.2.12 string DeviceProxy::adm_name()

Returns the name of the corresponding administrator device. This is useful if you need to send an administration command to the device server e.g. restart it.

*Exception: ConnectionFailed, CommunicationFailed*

6.1.2.13 string DeviceProxy::dev_name()

Return the device name as it is stored locally

6.1.2.14 string DeviceProxy::description()

Returns the device description as a string.

*Exception: ConnectionFailed, CommunicationFailed*
6.1.2.15  DbDevImportInfo DeviceProxy::import_info()

Query the device for import info from the database. This method returns a DbDevImplInfo type. The DbDevImportInfo type is a struct defined as follows:

```cpp
class DbDevImportInfo {
    public:
        string name;
        long exported;
        string ior;
        string version; }
```

*Exception: NonDbDevice*

6.1.2.16  void DeviceProxy::set_transparency_reconnection(bool flag)

If flag is true, no exception will be thrown in case of network communication error between client and server. The API will try to re-build the network connection between client and server as soon as an error is detected. See 6.17 more more details on reconnection and exception.

6.1.2.17  bool DeviceProxy::get_transparency_reconnection()

Returns the transparency reconnection flag.

6.1.2.18  string DeviceProxy::alias()

Returns the device alias name if one is defined otherwise, throws a DevFailed exception with the reason field set to Db_AliasNotDefined.

6.1.3  Synchronous command oriented methods

6.1.3.1  CommandInfo DeviceProxy::command_query(string command)

Query the device for information about a single command. This command returns a single CommandInfo type. The CommandInfo type is a struct described in command_list_query().

*Exception: ConnectionFailed, CommunicationFailed, DevFailed from device*

6.1.3.2  CommandInfoList *DeviceProxy::command_list_query()

Query the device for info on all commands. This method returns a vector of CommandInfo types. This method allocates memory for the vector of CommandInfo returned to the caller. It is the caller responsibility to delete this memory. The CommandInfo type is a struct defined as follows:

```cpp
typedef _CommandInfo {
    string cmd_name;      /* command name as ascii string */
    long   cmd_tag;       /* command as binary value (for TACO) */
    long   in_type;       /* in type as binary value */
    long   out_type;      /* out type as binary value */
    string in_type_desc;  /* description of in type (optional) */
    string out_type_desc; /* description of out type (optional) */
};
```
CHAPTER 6. THE TANGO C++ APPLICATION PROGRAMMER INTERFACE

Tango::DispLevel disp_level; /* Command display level */
} CommandInfo;
typedef CommandInfoList vector<CommandInfo>;

Exception: ConnectionFailed, CommunicationFailed, DevFailed from device

6.1.3.3 DeviceData DeviceProxy::command_inout(string)
Execute a command on a device which takes no input arguments (void). The result is returned in a DeviceData object (cf. below how to insert and extract data from DeviceData).
Exception: ConnectionFailed, CommunicationFailed, DevFailed from device

6.1.3.4 DeviceData DeviceProxy::command_inout(const char *)
Idem previous call

6.1.3.5 DeviceData Deviceproxy::command_inout(string, DeviceData &)
Execute a command on a device. Input arguments are passed in a DeviceData object, output is returned as a DeviceData object (see below how to insert and extract data from DeviceData).
Exception: ConnectionFailed, CommunicationFailed, DevFailed from device

6.1.3.6 DeviceData DeviceProxy::command_inout(const char *, DeviceData &)
Idem previous call

6.1.3.7 vector<DeviceDataHistory> *command_history(string &, int)
Retrieve command history from the command polling buffer. The first argument is the command name. The second argument is the wanted history depth. This method returns a vector of DeviceDataHistory types. This method allocates memory for the vector of DeviceDataHistory returned to the caller. It is the caller responsibility to delete this memory. Class DeviceDataHistory is detailed on chapter 6.3. See chapter on Advanced Feature for all details regarding polling

DeviceProxy dev = new DeviceProxy("...");
vector<DeviceDataHistory> *hist;
hist = dev->command_history("Status", 5);
for (int i = 0; i < 5; i++)
{
    bool fail = (*hist)[i].failed();
    if (fail == false)
    {
        string str;
        (*hist)[i] >> str;
        cout << "Status = " << str << endl;
    }
    else
    {
        cout << "Command failed !" << endl;
        cout << "Error level 0 desc = " << ((*hist)[i].errors())[0].desc << endl;
    }
    cout << "Date = " << (*hist)[i].date().tv_sec << endl;
\}
delete hist;

---

**Exception:** NonSupportedFeature, ConnectionFailed, CommunicationFailed, DevFailed from device

6.1.3.8 DeviceDataHistoryList *command_history(const char *, int)
Idem previous call

6.1.4 Synchronous attribute related methods

6.1.4.1 Compatibility between Tango release 4 and release 5 regarding attribute properties

Between Tango V4 and Tango V5, attribute configuration has been modified to incorporate alarm and event related parameters. This explains why it exists two structure types for attribute configuration parameters. All Tango V4 parameters are defined in a structure called AttributeInfo and a new structure called AttributeInfoEx has been defined for all Tango V5 parameters. Nevertheless, AttributeInfoEx inherits from AttributeInfo and it is always possible to call the Tango V5 DeviceProxy::attribute_query() method and to store its result in one AttributeInfo structure thus allowing compatibility for client written for Tango V4 but linked with Tango V5. It is also possible for a client written and linked with Tango V5 to call Tango V5 DeviceProxy::attribute_query() method to all kind of Tango devices. For device using Tango V4, the alarm and event related parameters will be retrieved from the database instead of from the device.

6.1.4.2 AttributeInfoEx DeviceProxy::attribute_query(string attribute)
Query the device for information about a single attribute. This command returns a single AttributeInfoEx type which inherits from the AttributeInfo type. The AttributeInfoEx and AttributeInfo types are structures described in get_attribute_config() and get_attribute_config_ex().

**Exception:** ConnectionFailed, CommunicationFailed, DevFailed from device

6.1.4.3 AttributeInfoList * DeviceProxy::attribute_list_query()
Query the device for info on all attributes. This method returns a vector of AttributeInfo types. The AttributeInfo type is a structure described in get_attribute_config(). This method allocates memory for the vector of AttributeInfo structures returned to the caller. It is the caller responsibility to delete this memory.

6.1.4.4 AttributeInfoListEx * DeviceProxy::attribute_list_query_ex()
Query the device for info on all attributes. This method returns a vector of AttributeInfoEx types. The AttributeInfoEx type is a structure described in get_attribute_config_ex(). This method allocates memory for the vector of AttributeInfoEx structures returned to the caller. It is the caller responsibility to delete this memory.

6.1.4.5 vector<string> *DeviceProxy::get_attribute_list()
Return the names of all attributes implemented for this device as a vector of strings. This method allocates memory for the vector of strings returned to the caller. It is the caller responsibility to delete this memory.

**Exception:** ConnectionFailed, CommunicationFailed, DevFailed from device
6.1.4.6  AttributeInfoList *DeviceProxy::get_attribute_config(vector<string>&)

Return the attribute configuration for the list of specified attributes. To get all the attributes pass a vector containing the string AllAttr (defined in tango_const.h). This method allocates memory for the vector of AttributeInfo returned to the caller. It is the caller responsibility to delete this memory. AttributeInfo is a struct defined as follows:

```cpp
typedef struct _AttributeInfo
{
    string name;
    AttrWriteType writable;
    AttrDataFormat data_format;
    int data_type;
    int max_dim_x;
    int max_dim_y;
    string description;
    string label;
    string unit;
    string standard_unit;
    string display_unit;
    string format;
    string min_value;
    string max_value;
    string min_alarm;
    string max_alarm;
    string writable_attr_name;
    vector<string> extensions;
    Tango::DispLevel disp_level;
} AttributeInfo;
```

Exception: ConnectionFailed, CommunicationFailed, DevFailed from device

6.1.4.7  AttributeInfoListEx *DeviceProxy::get_attribute_config_ex(vector<string>&)

Return the extended attribute configuration for the list of specified attributes. To get all the attributes pass a vector containing the string AllAttr (defined in tango_const.h). This method allocates memory for the vector of AttributeInfoEx returned to the caller. It is the caller responsibility to delete this memory. AttributeInfoEx is a structure defined as follows:

```cpp
struct AttributeInfoEx: public AttributeInfo
{
    AttributeAlarmInfo alarms;
    AttributeEventInfo events;
    vector<string> sys_extensions;
};

struct AttributeAlarmInfo
{
    string min_alarm;
    string max_alarm;
};
```
string min_warning;
string max_warning;
string delta_t;
string delta_val;
vector<string> extensions;
);

struct AttributeEventInfo
{
    ChangeEventInfo ch_event;
    PeriodicEventInfo per_event;
    ArchiveEventInfo arch_event;
};

struct ChangeEventInfo
{
    string rel_change;
    string abs_change;
    vector<string> extensions;
};

struct PeriodicEventInfo
{
    string period;
    vector<string> extensions;
};

struct ArchiveEventInfo
{
    string archive_rel_change;
    string archive_abs_change;
    string archive_period;
    vector<string> extensions;
};

Exception: ConnectionFailed, CommunicationFailed, DevFailed from device

6.1.4.8 AttributeInfoEx DeviceProxy::get_attribute_config(string&)
Return the attribute configuration for a single attributes. The AttributeInfoEx is a structure defined above.
Exception: ConnectionFailed, CommunicationFailed, DevFailed from device

6.1.4.9 void DeviceProxy::set_attribute_config(AttributeInfoList &)
Change the attribute configuration for the specified attributes.
Exception: ConnectionFailed, CommunicationFailed, DevFailed from device

6.1.4.10 void DeviceProxy::set_attribute_config(AttributeInfoListEx &)
Change the attribute configuration for the specified attributes.
Exception: ConnectionFailed, CommunicationFailed, DevFailed from device
6.1.4.11 vector<DeviceAttribute>*DeviceProxy::read_attributes(vector<string>&)

Read the list of specified attributes. To extract the value you have to use the operator of the
class DeviceAttribute which corresponds to the data type of the attribute. NOTE: There is no
automatic type conversion from the attribute native type to user type e.g. if an attribute returns
a short you cannot extract it as a double, you have to extract it as a short. By default, if the
server reports error for one of the attribute in the list, this error will be passed to the user using
exception when he (she) will try to extract the data form the corresponding See sub-chapter on
DeviceAttribute to learn how to change this default behaviour. DeviceAttribute object. This
method allocates memory for the vector of DeviceAttribute objects returned to the caller. This is
the caller responsibility to delete this memory. Example:

```
vector<DeviceAttribute>* devattr;
vector<string> attr_names;

attr_names.push_back("attribute_1");
attr_names.push_back("attribute_2");
devattr = device->read_attributes(attr_names);
short short_attr_1;
long long_attr_2;
(*devattr)[0] >> short_attr_1;
(*devattr)[1] >> long_attr_2;
cout << "my_attribute value " << short_attr;
delete devattr;
```

*Exception: ConnectionFailed, CommunicationFailed*

6.1.4.12 DeviceAttribute DeviceProxy::read_attribute(string&)

Read a single attribute. To extract the value you have to use the operator of the class DeviceAt-
tribute which corresponds to the data type of the attribute. NOTE: There is no automatic type
conversion from the attribute native type to user type e.g. if an attribute returns a short you
cannot extract it as a double (this will return 0) you have to extract it as a short. See example
above.

*Exception: ConnectionFailed, CommunicationFailed*

6.1.4.13 DeviceAttribute DeviceProxy::read_attribute(const char *)

Idem previous call

6.1.4.14 void DeviceProxy::write_attributes(vector<DeviceAttribute>&)

Write the specified attributes. To insert the values to write you have to use the operator of the
DeviceAttribute class which corresponds to the data type of the attribute. NOTE: There is no
automatic type conversion from the user type to the attribute native type e.g. if an attribute
expects a short you cannot insert it as a double (this will throw an exception) you have to insert it
as a short. Note that this is the only API call which could throw a NamedDevFailedList exception.
See 6.16.10 to get all the details on this exception. Example:
vector<DeviceAttribute> attr_in;
string att1_name("First_attr");
string att2_name("Second_attr");
short short_attr;
double double_attr; attr_in.push_back(DeviceAttribute(att1_name, short_attr));
attr_in.push_back(DeviceAttribute(att2_name, double_attr));
device->write_attributes(attr_in);

Exception: ConnectionFailed, CommunicationFailed, DevFailed or NamedDevFailedList from device

6.1.4.15 void DeviceProxy::write_attribute(DeviceAttribute&)

Write a single attribute. To insert the value to write you have to use the operator of the class DeviceAttribute which corresponds to the data type of the attribute. NOTE: There is no automatic type conversion from the user type to the attribute native type e.g. if an attribute expects a short you cannot insert it as a double (this will throw an exception) you have to insert it as a short. See example above.

Exception: ConnectionFailed, CommunicationFailed, DevFailed from device

6.1.4.16 vector<DeviceAttributeHistory> *DeviceProxy::attribute_history(string &, int)

Retrieve attribute history from the attribute polling buffer. The first argument is the attribute name. The second argument is the wanted history depth. This method returns a vector of DeviceAttributeHistory types. This method allocates memory for the vector of DeviceAttributeHistory returned to the caller. It is the caller responsibility to delete this memory. Class DeviceAttributeHistory is detailed on chapter 6.5. See also chapter on Advanced Feature for all details regarding polling.

DeviceProxy dev = new DeviceProxy("...");
vector<DeviceAttributeHistory> *hist;
hist = dev->attribute_history("Current", 5);
for (int i = 0; i < 5; i++)
{
  bool fail = (*hist)[i].has_failed();
  if (fail == false)
  {
    cout << "Attribute name = " << (*hist)[i].get_name() << endl;
    cout << "Attribute quality factor = " << (*hist)[i].get_quality() << endl;
    long value;
    (*hist)[i] >> value;
    cout << "Current = " << value << endl;
  }
  else
  {
    cout << "Attribute failed !" << endl;
    cout << "Error level 0 desc = " << (((*hist)[i].get_err_stack())[0].desc << endl;
  }
cout << "Date = " << (*hist)[i].get_date().tv_sec << endl;
}
delete hist;

Exception: NonSupportedFeature, ConnectionFailed, CommunicationFailed, DevFailed from device

6.1.4.17 vector<DeviceAttributeHistory> *DeviceProxy::attribute_history(const char *, int)
Idem previous call

6.1.5 Asynchronous command oriented methods

6.1.5.1 long DeviceProxy::command_inout_asynch(string &name, bool forget)
Execute asynchronously (polling model) a command on a device which takes no input argument. The last argument is a fire and forget flag. If this flag is set to true, this means that the client does not care at all about the server answer and will even not try to get it. A false default value is provided. Please, note that device re-connection will not take place (in case it is needed) if the fire and forget mode is used. Therefore, an application using only fire and forget requests is not able to automatically re-connect to device. This call returns an asynchronous call identifier which is needed to get the command result.
Exception: ConnectionFailed

6.1.5.2 long DeviceProxy::command_inout_asynch(const char *name, bool forget)
Idem previous call

6.1.5.3 long DeviceProxy::command_inout_asynch(string &name, DeviceData &argin, bool forget)
Execute asynchronously (polling model) a command on a device. Input arguments are passed in a DeviceData object (see following chapters on how to insert data into DeviceData object). The last argument is a fire and forget flag. If this flag is set to true, this means that the client does not care at all about the server answer and will even not try to get it. A false default value is provided. Please, note that device re-connection will not take place (in case it is needed) if the fire and forget mode is used. Therefore, an application using only fire and forget requests is not able to automatically re-connect to device. This call returns an asynchronous call identifier which is needed to get the command result.
Exception: ConnectionFailed

6.1.5.4 long DeviceProxy::command_inout_asynch(const char *name, DeviceData &argin, bool forget)
Idem previous call

6.1.5.5 DeviceData DeviceProxy::command_inout_reply(long id)
Check if the answer of an asynchronous command_inout is arrived (polling model). id is the asynchronous call identifier. If the reply is arrived and if it is a valid reply, it is returned to the caller in a DeviceData object. If the reply is an exception, it is re-thrown by this call. An exception is also thrown in case of the reply is not yet arrived. Example:
Tango::DeviceProxy dev("...");
long asyn_id;
asyn_id = dev.command_inout_asynch("MyCmd");
...
...
Tango::DeviceData arg;
try {
    arg = dev.command_inout_reply(asyn_id);
}
catch(Tango::AsynReplyNotArrived)
{
    cerr << "Command not arrived !" << endl;
}
catch (Tango::DevFailed &e)
{
    Tango::Except::print_exception(e);
}

Exception: AsynCall, AsynReplyNotArrived, CommunicationFailed, DevFailed from device

6.1.5.6 DeviceData DeviceProxy::command_inout_reply(long id, long timeout)
Check if the answer of an asynchronous command_inout is arrived (polling model). id is the synchronous call identifier. If the reply is arrived and if it is a valid reply, it is returned to the caller in a DeviceData object. If the reply is an exception, it is re-thrown by this call. If the reply is not yet arrived, the call will wait (blocking the process) for the time specified in timeout. If after timeout milliseconds, the reply is still not there, an exception is thrown. If timeout is set to 0, the call waits until the reply arrived.

Exception: AsynCall, AsynReplyNotArrived, CommunicationFailed, DevFailed from device

6.1.5.7 void DeviceProxy::command_inout_asynch(string &name, Callback &cb)
Execute asynchronously (callback model) a command on a device which takes no input argument. The last argument is a reference to a callback object. This callback object should be an instance of a user class inheriting from the Tango::CallBack class with the cmd_ended() method overloaded.

Exception: ConnectionFailed

6.1.5.8 void DeviceProxy::command_inout_asynch(const char *name, Callback &cb)
Idem previous call

6.1.5.9 void DeviceProxy::command_inout_asynch(string &name, DeviceData &arg, CallBack &cb)
Execute asynchronously (callback model) a command on a device. Input arguments are passed in a DeviceData object (see following chapters on how to insert data into DeviceData object). The last argument is a reference to a callback object. This callback object should be an instance of a user class inheriting from the Tango::CallBack class with the cmd_ended() method overloaded.

Exception: ConnectionFailed
6.1.5.10  void DeviceProxy::command_inout_async(const char *name, DeviceData &argin, Callback &cb)

Idem previous call

6.1.6  Asynchronous attribute related methods

6.1.6.1  long DeviceProxy::read_attribute_async(string &name)

Read asynchronously (polling model) a single attribute. This call returns an asynchronous call identifier which is needed to get the attribute value.

_exception: ConnectionFailed

6.1.6.2  long DeviceProxy::read_attribute_async(const char *name)

Idem previous call

6.1.6.3  long DeviceProxy::read_attributes_async(vector<string> &names)

Read asynchronously (polling model) the list of specified attributes. This call returns an asynchronous call identifier which is needed to get attributes value.

_exception: ConnectionFailed

6.1.6.4  DeviceAttribute *DeviceProxy::read_attribute_reply(long id)

Check if the answer of an asynchronous read_attribute is arrived (polling model). _id is the asynchronous call identifier. If the reply is arrived and if it is a valid reply, it is returned to the caller in a DeviceAttribute object. If the reply is an exception, it is re-thrown by this call. An exception is also thrown in case of the reply is not yet arrived. To extract attribute value, you have to use the operator of the class DeviceAttribute which corresponds to the data type of the attribute. NOTE: There is no automatic type conversion from the attribute native type to user type e.g. if an attribute returns a short you cannot extract it as a double, you have to extract it as a short. Memory has been allocated for the DeviceAttribute object returned to the caller. This is the caller responsibility to delete this memory.

_exception: AsynCall, AsynReplyNotArrived, CommunicationFailed, DevFailed from device

6.1.6.5  DeviceAttribute *DeviceProxy::read_attribute_reply(long id, long timeout)

Check if the answer of an asynchronous read_attribute is arrived (polling model). _id is the asynchronous call identifier. If the reply is arrived and if it is a valid reply, it is returned to the caller in a DeviceAttribute object. If the reply is an exception, it is re-thrown by this call. If the reply is not yet arrived, the call will wait (blocking the process) for the time specified in timeout. If after timeout milliseconds, the reply is still not there, an exception is thrown. If timeout is set to 0, the call waits until the reply arrived. To extract attribute value, you have to use the operator of the class DeviceAttribute which corresponds to the data type of the attribute. NOTE: There is no automatic type conversion from the attribute native type to user type e.g. if an attribute returns a short you cannot extract it as a double, you have to extract it as a short. Memory has been allocated for the DeviceAttribute object returned to the caller. This is the caller responsibility to delete this memory.

_exception: AsynCall, AsynReplyNotArrived, CommunicationFailed, DevFailed from device
6.1.6.6 vector<DeviceAttribute>*DeviceProxy::read_attributes_reply(long id)

Check if the answer of an asynchronous read_attributes is arrived (polling model). id is the asynchronous call identifier. If the reply is arrived and if it is a valid reply, it is returned to the caller in a vector<DeviceAttribute>. If the reply is an exception, it is re-thrown by this call. An exception is also thrown in case of the reply is not yet arrived. To extract attribute value, you have to use the operator of the class DeviceAttribute which corresponds to the data type of the attribute. NOTE: There is no automatic type conversion from the attribute native type to user type e.g. if an attribute returns a short you cannot extract it as a double, you have to extract it as a short. Memory has been allocated for the vector<DeviceAttribute> object returned to the caller. This is the caller responsibility to delete this memory.

_exception: AsynCall, AsynReplyNotArrived, CommunicationFailed, DevFailed from device

6.1.6.7 vector<DeviceAttribute>*DeviceProxy::read_attributes_reply(long id, long timeout)

Check if the answer of an asynchronous read_attributes is arrived (polling model). id is the asynchronous call identifier. If the reply is arrived and if it is a valid reply, it is returned to the caller in a vector<DeviceAttribute>. If the reply is an exception, it is re-thrown by this call. If the reply is not yet arrived, the call will wait (blocking the process) for the time specified in timeout. If after timeout milliseconds, the reply is still not there, an exception is thrown. If timeout is set to 0, the call waits until the reply arrived. To extract attribute value, you have to use the operator of the class DeviceAttribute which corresponds to the data type of the attribute. NOTE: There is no automatic type conversion from the attribute native type to user type e.g. if an attribute returns a short you cannot extract it as a double, you have to extract it as a short. Memory has been allocated for the vector<DeviceAttribute> object returned to the caller. This is the caller responsibility to delete this memory.

_exception: AsynCall, AsynReplyNotArrived, CommunicationFailed, DevFailed from device

6.1.6.8 long DeviceProxy::write_attribute_asynch(DeviceAttribute &argin)

Write asynchronously (polling model) a single attribute. To insert the value to write you have to use the operator of the class DeviceAttribute which corresponds to the data type of the attribute. NOTE: There is no automatic type conversion from the user type to the attribute native type e.g. if an attribute expects a short you cannot insert it as a double (this will throw an exception) you have to insert it as a short. This call returns an asynchronous call identifier which is needed to get the server reply.

_exception: ConnectionFailed

6.1.6.9 long DeviceProxy::write_attributes_asynch(vector<DeviceAttribute> &argin)

Write asynchronously (polling model) the specified attributes. To insert the value to write you have to use the operator of the class DeviceAttribute which corresponds to the data type of the attribute. NOTE: There is no automatic type conversion from the user type to the attribute native type e.g. if an attribute expects a short you cannot insert it as a double (this will throw an exception) you have to insert it as a short. This call returns an asynchronous call identifier which is needed to get the server reply.

_exception: ConnectionFailed

6.1.6.10 void DeviceProxy::write_attribute_reply(long id)

Check if the answer of an asynchronous write_attribute is arrived (polling model). id is the asynchronous call identifier. If the reply is arrived and if it is a valid reply, the call returned. If
the reply is an exception, it is re-thrown by this call. An exception is also thrown in case of the reply is not yet arrived.

Exception: AsynCall, AsynReplyNotArrived, CommunicationFailed, DevFailed from device

6.1.6.11 void DeviceProxy::write_attribute_reply(long id, long timeout)
Check if the answer of an asynchronous write_attribute is arrived (polling model). id is the asynchronous call identifier. If the reply is arrived and if it is a valid reply, the call returned. If the reply is an exception, it is re-thrown by this call. If the reply is not yet arrived, the call will wait (blocking the process) for the time specified in timeout. If after timeout milliseconds, the reply is still not there, an exception is thrown. If timeout is set to 0, the call waits until the reply arrived.

Exception: AsynCall, AsynReplyNotArrived, CommunicationFailed, DevFailed from device

6.1.6.12 void DeviceProxy::write_attributes_reply(long id)
Check if the answer of an asynchronous write_attributes is arrived (polling model). id is the asynchronous call identifier. If the reply is arrived and if it is a valid reply, the call returned. If the reply is an exception, it is re-thrown by this call. An exception is also thrown in case of the reply is not yet arrived.

Exception: AsynCall, AsynReplyNotArrived, CommunicationFailed, DevFailed from device

6.1.6.13 void DeviceProxy::write_attributes_reply(long id, long timeout)
Check if the answer of an asynchronous write_attributes is arrived (polling model). id is the asynchronous call identifier. If the reply is arrived and if it is a valid reply, the call returned. If the reply is an exception, it is re-thrown by this call. If the reply is not yet arrived, the call will wait (blocking the process) for the time specified in timeout. If after timeout milliseconds, the reply is still not there, an exception is thrown. If timeout is set to 0, the call waits until the reply arrived.

Exception: AsynCall, AsynReplyNotArrived, CommunicationFailed, DevFailed from device

6.1.6.14 void DeviceProxy::read_attribute_asynch(string &name, CallBack &cb)
Read asynchronously (callback model) a single attribute. The last argument is a reference to a callback object. This callback object should be an instance of a user class inheriting from the Tango::CallBack class with the attr_read() method overloaded.

Exception: ConnectionFailed

6.1.6.15 void DeviceProxy::read_attribute_asynch(const char *name, CallBack &cb)
Idem previous call

6.1.6.16 void DeviceProxy::read_attributes_asynch(vector<string> &names, CallBack &cb)
Read asynchronously (callback model) an attribute list. The last argument is a reference to a callback object. This callback object should be an instance of a user class inheriting from the Tango::CallBack class with the attr_read() method overloaded.

Exception: ConnectionFailed
6.1.6.17  void DeviceProxy::write_attribute_asynch(DeviceAttribute &argin, Call-Back &cb)
Write asynchronously (callback model) a single attribute. The last argument is a reference to a callback object. This callback object should be an instance of a user class inheriting from the Tango::CallBack class with the attr_written() method overloaded.
   Exception: ConnectionFailed

6.1.6.18  void DeviceProxy::write_attributes_asynch(vector<DeviceAttribute> &argin, CallBack &cb)
Write asynchronously (callback model) an attribute list. The last argument is a reference to a callback object. This callback object should be an instance of a user class inheriting from the Tango::CallBack class with the attr_written() method overloaded.
   Exception: ConnectionFailed

6.1.7  Miscellaneous asynchronous related methods
6.1.7.1  long DeviceProxy::pending_async_call(asyn_req_type req)
Return number of device asynchronous pending requests. The input parameter is an enumeration with three values which are:

POLLING : Returns only device polling model asynchronous request number
CALLBACK : Returns only device callback model asynchronous request number
ALL_ ASYNCH : Returns device asynchronous request number
   Exception: None

6.1.7.2  void DeviceProxy::get_async_replies()
Fire callback methods for device asynchronous requests with already arrived replied. Returns immediately if there is no replies already arrived or if there is no asynchronous request for the device :

```cpp
class MyCallBack: Tango::CallBack
{
public:
   MyCallback(double d):data(d) {};
   virtual void cmd ended(Tango::CmdDoneEvent *)
   private:
   double data;
};

void MyCallBack::cmd ended(Tango CmdDoneEvent *cmd)
{
   if (cmd->err == true)
      Tango::Except::print_error_stack(cmd->errors);
   else
   {
      short cmd_result;
      cmd->argout >> cmd_result;
      cout << "Command result = " << cmd_result << endl;
```

cout << "Callback personal data = " << data << endl;
}
}

int main(int argc, char *argv[])
{
    ...
    ...
    Tango::DeviceProxy dev("...");
    double my_data = ...;
    MyCallBack cb(my_data);
    dev.command_inout_asynch("MyCmd", cb);
    ...
    ...
    dev.get_async_replies();
    ...
    ...
}

Exception: None, all errors are reported using the err and errors fields of the parameter passed to the callback method. See chapter 6.8 for details.

6.1.7.3 void DeviceProxy::get_async_replies(long timeout)
Fire callback methods for device asynchronous requests (command and attributes) with already arrived replies. Wait and block the caller for timeout milliseconds if they are some device asynchronous requests which are not yet arrived. Returns immediately if there is no asynchronous request for the device. If timeout is set to 0, the call waits until all the asynchronous requests sent to the device has received a reply.

Exception: AsyncReplyNotArrived. All other errors are reported using the err and errors fields of the object passed to the callback methods. See chapter 6.8 for details.

6.1.8 Polling related methods

6.1.8.1 bool DeviceProxy::is_command_poled(string &cmd_name)
Returns true if the command "cmd_name" is polled. Otherwise, returns false.

6.1.8.2 bool DeviceProxy::is_command_poled(const char *cmd_name)
Idem previous call

6.1.8.3 bool DeviceProxy::is_attribute_poled(string &attr_name)
Returns true if the attribute "attr_name" is polled. Otherwise, returns false.

6.1.8.4 bool DeviceProxy::is_attribute_poled(const char *attr_name)
Idem previous call

6.1.8.5 int DeviceProxy::get_command_poll_period(string &cmd_name)
Returns the command "cmd_name" polling period in mS. If the command is not polled, it returns 0.
6.1.8.6 int DeviceProxy::get_command_poll_period(const char *cmd_name)
Idem previous call

6.1.8.7 int DeviceProxy::get_attribute_poll_period(string &attr_name)
Returns the attribute "attr_name" polling period in mS. If the attribute is not polled, it returns 0.

6.1.8.8 int DeviceProxy::get_attribute_poll_period(const char *attr_name)
Idem previous call

6.1.8.9 vector<string> *DeviceProxy::polling_status()
Returns the device polling status. There is one string for each polled command/attribute. Each string is multi-line string with:

- The attribute/command name
- The attribute/command polling period (in mS)
- The attribute/command polling ring buffer depth
- The time needed for the last command/attribute execution (in mS)
- The time since data in the ring buffer has not been updated
- The delta time between the last records in the ring buffer
- The exception parameters in case of the last command/attribute execution failed

This method allocates memory for the vector of string(s) returned to the caller. It is the caller responsibility to delete this memory.

6.1.8.10 void DeviceProxy::poll_command(string &cmd_name, int period)
Add the command "cmd_name" to the list of polled commands. The polling period is specified by "period" (in mS). If the command is already polled, this method will update the polling period according to "period".

6.1.8.11 void DeviceProxy::poll_command(const char *cmd_name, int period)
Idem previous call

6.1.8.12 void DeviceProxy::poll_attribute(string &attr_name, int period)
Add the attribute "attr_name" to the list of polled attributes. The polling period is specified by "period" (in mS). If the attribute is already polled, this method will update the polling period according to "period".

6.1.8.13 void DeviceProxy::poll_attribute(const char *attr_name, int period)
Idem previous call

6.1.8.14 void DeviceProxy::stop_poll_command(string &cmd_name)
Remove command "cmd_name" from the list of polled command.
6.1.8.15 `void DeviceProxy::stop_poll_command(const char *cmd_name)`
Idem previous call

6.1.8.16 `void DeviceProxy::stop_poll_attribute(string &attr_name)`
Remove attribute "attr_name" from the list of polled attributes.

6.1.8.17 `void DeviceProxy::stop_poll_attribute(const char *attr_name)`
Idem previous call

6.1.9 Event related methods

6.1.9.1 `int DeviceProxy::subscribe_event(const string &attribute, EventType event, CallBack *cb, const vector<string> &filters)`
The client call to subscribe to an event. The client implements a callback method which is triggered when the event is received either by polling or a dedicated thread. Filtering is done based on the reason specified and the event type. For example when reading the state and the reason specified is "change" the event will be fired only when the state changes. Events consist of an attribute name and the event reason. A standard set of reasons are implemented by the system, additional device specific reasons can be implemented by device servers programmers.

The `attribute` parameter is the device attribute name which will be sent as an event e.g. "current", `event` parameter is the event reason and must be on the enumerated values:

- Tango::CHANGE_EVENT
- Tango::PERIODIC_EVENT
- Tango::QUALITY_EVENT
- Tango::ARCHIVE_EVENT
- Tango::USER_EVENT

`cb` is a pointer to a class inheriting from the Tango CallBack class and implementing a `push_event()` method, `filters` is a variable list of name,value pairs which define additional filters for events. In the first implementation of the Tango event system this parameter is ignored. The `subscribe_event()` call returns an event id which has to be specified when unsubscribing from this event. Please note that the `cb` parameter is a pointer. The lifetime of the pointed to object must at least be equal to the time when events are requested because only the pointer is stored into the event machinery. The same thing is true for the DeviceProxy instance on which the `subscribe_event()` method is called.

*Exception: EventSystemFailed*

6.1.9.2 `void DeviceProxy::unsubscribe_event(int event_id)`
Unsubscribe a client from receiving the event specified by `event_id`. `event_id` is the event identifier returned by the `DeviceProxy::subscribe_event()` method.

*Exception: EventSystemFailed*

6.1.10 Property related methods

6.1.10.1 `void DeviceProxy::get_property (string&, DbData&)` Get a single property for a device. The property to get is specified as a string. Refer to DbDevice:get_property() and DbData sections below for details on the DbData type.

*Exception: NonDbDevice, ConnectionFailed (with database), CommunicationFailed (with database), DevFailed from database device*
CHAPTER 6. THE TANGO C++ APPLICATION PROGRAMMER INTERFACE

6.1.10.2 void DeviceProxy::get_property (vector<string> &, DbData &)
Get a list of properties for a device. The properties to get are specified as a vector of strings. Refer to DbDevice::get_property() and DbData sections below for details on the DbData type.

Exception: NonDbDevice, ConnectionFailed (with database), CommunicationFailed (with database),
DevFailed from database device

6.1.10.3 void DeviceProxy::get_property(DbData &)
Get property(ies) for a device. Properties to get are specified using the DbData type. Refer to DbDevice::get_property() and DbData sections below for details.

Exception: NonDbDevice, ConnectionFailed (with database), CommunicationFailed (with database),
DevFailed from database device

6.1.10.4 void DeviceProxy::put_property(DbData &)
Put property(ies) for a device. Properties to put are specified using the DbData type. Refer to DbDevice::put_property() and DbData sections below for details.

Exception: NonDbDevice, ConnectionFailed (with database), CommunicationFailed (with database),
DevFailed from database device

6.1.10.5 void DeviceProxy::delete_property (string &, DbData &)
Delete a single property for a device. The property to delete is specified as a string. Refer to DbDevice::delete_property() and DbData sections below for details on the DbData type.

Exception: NonDbDevice, ConnectionFailed (with database), CommunicationFailed (with database),
DevFailed from database device

6.1.10.6 void DeviceProxy::delete_property (vector<string> &, DbData &)
Delete a list of properties for a device. The properties to delete are specified as a vector of strings. Refer to DbDevice::get_property() and DbData sections below for details on the DbData type.

Exception: NonDbDevice, ConnectionFailed (with database), CommunicationFailed (with database),
DevFailed from database device

6.1.10.7 void DeviceProxy::delete_property(DbData &)
Delete property(ies) for a device. Properties to delete are specified using the DbData type. Refer to DbDevice::get_property() and DbData sections below for details.

Exception: NonDbDevice, ConnectionFailed (with database), CommunicationFailed (with database),
DevFailed from database device

6.1.11 Logging related methods

6.1.11.1 void DeviceProxy::add_logging_target (const string &target_type &target_name)
Adds a new logging target to the device. The target_type & target_name input parameter must follow the format: target_type::target_name. Supported target types are: console, file and device. For a device target, the target_name part of the target_type::target_name parameter must contain the name of a log consumer device (as defined in A.7). For a file target, target_name is the full path to the file to log to. If omitted, the device’s name is used to build the file name (which is something like domain_family_member.log). Finally, the target_name part of the target_type::target_name input parameter is ignored in case of a console target and can be omitted.

Exception: DevFailed from device
6.1.11.2  void DeviceProxy::add_logging_target (const char *target_type_target_name)
Idem previous call

6.1.11.3  void DeviceProxy::remove_logging_target (const string &target_type_target_name)
Removes a logging target from the device’s target list. The target_type_target_name input parameter must follow the format: target_type::target_name. Supported target types are: console, file and device. For a device target, the target_name part of the target_type_target_name parameter must contain the name of a log consumer device (as defined in ). For a file target, target_name is the full path to the file to remove. If omitted, the default log file is removed. Finally, the target_name part of the target_type_target_name input parameter is ignored in case of a console target and can be omitted.
If target_name is set to "**", all targets of the specified target_type are removed.

6.1.11.4  void DeviceProxy::remove_logging_target (const char *target_type_target_name)
Idem previous call

6.1.11.5  vector<string> DeviceProxy::get_logging_target ()
Returns a vector of string containing the current device's logging targets. Each vector element has the following format: target_type::target_name. An empty vector is returned if the device has no logging targets.

6.1.11.6  int DeviceProxy::get_logging_level ()
Returns the current device’s logging level (0=OFF, 1=FATAL, 2=ERROR, 3=WARNING, 4=INFO, 5=DEBUG).

6.1.11.7  void DeviceProxy::set_logging_level (int level)
Changes the device’s logging level. (0=OFF, 1=FATAL, 2=ERROR, 3=WARNING, 4=INFO, 5=DEBUG).

6.2  Tango::DeviceData

This is the fundamental type for sending and receiving data from device commands. The values can be inserted and extracted using the operators < < and >> respectively and insert() for mixed data types. A status flag indicates if there is data in the DbDatum object or not. An additional flag allows the user to activate exceptions.

6.2.1  Operators
The insert and extract operators are specified for the following C++ types:

1. bool
2. short
3. unsigned short
4. long
5. unsigned long
6. int
7. float
8. double
9. string
10. char* (insert only)
11. const char *
12. vector<unsigned char>
13. vector<string>
14. vector<short>
15. vector<unsigned short>
16. vector<long>
17. vector<unsigned long>
18. vector<float>
19. vector<double>

Operators exist for inserting and extracting the native TANGO CORBA sequence types. These can be useful for programmers who want to use the TANGO api internally in their device servers and do not want to convert from CORBA to C++ types. Insert and extract operators exist for the following types :

1. DevVarUCharArray *(const DevVarUCharArray * for extraction)
2. DevVarShortArray *(const DevVarShortArray * for extraction)
3. DevVarUShortArray *(const DevVarUShortArray * for extraction)
4. DevVarLongArray *(const DevVarLongArray * for extraction)
5. DevVarULongArray *(const DevVarULongArray * for extraction)
6. DevVarFloatArray *(const DevVarFloatArray * for extraction)
7. DevVarDoubleArray *(const DevVarDoubleArray * for extraction)
8. DevVarStringArray *(const DevVarStringArray * for extraction)
9. DevVarLongStringArray *(const DevVarLongStringArray * for extraction)
10. DevVarDoubleStringArray *(const DevVarDoubleStringArray * for extraction)

---

Note:
Insertion by pointers takes full ownership of the pointed to memory. The insertion copy the data in the DeviceData object and delete the pointed to memory. Therefore, the memory is not more usable after the insertion. Also note that when using extraction by pointers, the pointed to memory is inside the DeviceData object and its lifetime is the same than the DeviceData object lifetime.
Operators also exist for inserting TANGO CORBA sequence type by reference. The insertion copy the data into the DeviceData object. Insert operator exist for the following types:

1. DevVarUCharArray &
2. DevVarShortArray &
3. DevVarUShortArray &
4. DevVarLongArray &
5. DevVarULongArray &
6. DevVarFloatArray &
7. DevVarDoubleArray &
8. DevVarStringArray &
9. DevVarLongStringArray &
10. DevVarDoubleStringArray &

Additional methods exist for inserting a mixture of strings and long (Tango::DevVarLongStringArray) and string and doubles (Tango::DevVarDoubleStringArray). These are:

1. insert(vector<long>&, vector<string>&)
2. insert(vector<double>&, vector<string>&)
3. extract(vector<long>&, vector<string>&)
4. extract(vector<double>&, vector<string>&)

All the extraction methods returns a boolean set to false if the extraction has failed (empty DeviceData, wrong data type...)

Special care has been taken to avoid memory copy between the network layer and the user application. Nevertheless, C++ vector types are not the CORBA native type and one copy is unavoidable when using vectors. Using the native TANGO CORBA sequence types avoid any copy. When using these TANGO CORBA sequence types, insertion into the DeviceData object consumes the memory pointed to by the pointer. After the insertion, it is not necessary to delete the memory. It will be done by the destruction of the DeviceData object. For extraction, the pointer used for the extraction points into memory inside the DeviceData object and you should not delete it.

Here is an example of creating, inserting and extracting some data type from/into DeviceData object:

```cpp
DeviceData my_short, my_long, my_string;
DeviceData my_float_vector, my_double_vector;
string a_string;
short a_short;
long a_long;
vector<float> a_float_vector;
vector<double> a_double_vector;
my_short << 100; // insert a short
my_short >> a_short; // extract a short
my_long << 1000; // insert a long
my_long >> a_long; // extract a long
```
my_string << string("estas lista a bailar el tango?"); // insert a string
my_string >> a_string; // extract a string
my_float_vector << a_float_vector; // insert a vector of floats
my_float_vector >> a_float_vector; // extract a vector of floats
my_double_vector << a_double_vector; // insert a vector of doubles
my_double_vector >> a_double_vector; // extract a vector of doubles

// Example of memory management with TANGO sequence types without memory leaks
//
for (int i = 0;i < 10;i++)
{
    DeviceData din,dout;
    DevVarLongArray *in = new DevVarLongArray();
    in->length(2);
    (*in)[0] = 2;
    (*in)[1] = 4;
    din << in;
    try
    {
        dout = device->command_inout("Cmd",din);
    }
    catch(DevFailed &e)
    {
        ....
    }
    const DevVarLongArray *out;
    dout >> out;
    cout << "Received value =" << (*out)[0];
}

---

Exception: WrongData if requested

6.2.2 bool DeviceData::is_empty()

is_empty() is a boolean method which returns true or false depending on whether the DeviceData object contains data or not. It can be used to test whether the DeviceData has been initialized or not e.g.

```cpp
string string_read;
DeviceData sl_read = my_device->command_inout("ReadLine");
if (!sl_read.is_empty())
{
    sl_read >> string_read;
}
else
{
    cout << " no data read from serial line!" << endl;
}
```

---

Exception: WrongData if requested
6.2.3 int DeviceData::get_type()
This method returns the Tango data type of the data inside the DeviceData object

6.2.4 void DeviceData::exceptions(bitset <DeviceData::numFlags> )
Is a method which allows the user to switch on/off exception throwing when trying to extract data from an empty DeviceData object or using a wrong data type. The default is to not throw exception. The following flags are supported:

1. isempty_flag - throw a WrongData exception (reason = API_EmptyDeviceData) if user tries to extract data from an empty DeviceData object
2. wrongtype_flag - throw a WrongData exception (reason = API_IncompatibleCmdArgumentType) if user tries to extract data with a type different than the type used for insertion

6.2.5 bitset <DeviceData::numFlags> exceptions()
Returns the whole exception flags.

6.2.6 void DeviceData::reset_exceptions(DeviceData::except_flags fl)
Resets one exception flag

6.2.7 void DeviceData::set_exceptions(DeviceData::except_flags fl)
Sets one exception flag

The following is an example of how to use these exceptions related methods

```cpp
DeviceData da;
bitset<DeviceData::numFlags> bs = da.exceptions();
cout << "bs = " << bs << endl;
da.set_exceptions(DeviceData::wrongtype_flag);
bs = da.exceptions();
cout << "bs = " << bs << endl;
```

6.2.8 ostream &operator<<(ostream &, DeviceData &)
Is an utility function to easily print the contents of a DeviceData object. This function knows all types which could be inserted in a DeviceData object and print them accordingly. A special string is printed if the DeviceData object is empty

```cpp
DeviceProxy *dev = new DeviceProxy("...");
DeviceData out;
out = dev->command_inout("MyCommand");
cout << "Command returned: " << out << endl;
```
6.3 Tango::DeviceDataHistory

This is the fundamental type for receiving data from device command polling buffers. This class inherits from the Tango::DeviceData class. One instance of this class is created for each command result history. Within this class, you find the command result data or the exception parameters, a flag indicating if the command has failed when it was invoked by the device server polling thread and the date when the command was executed. For history calls, it is not possible to returns command error as exception. See chapter on Advanced Features for all details regarding device polling. On top of the methods inherited from the DeviceData class, it offers the following methods.

6.3.1 bool DeviceDataHistory::has_failed()

Returns true if the corresponding command has failed when it was executed by the device server polling thread. Otherwise returns false (amazing!)

Exception: none

6.3.2 TimeVal &DeviceDataHistory::get_date()

Returns the date when the device server polling thread has executed the command.

Exception: none

6.3.3 const DevErrorList &DeviceDataHistory::get_err_stack()

Return the error stack recorded by the device server polling thread in case of the command failed when it was invoked.

Exception: none

6.3.4 ostream &operator<<(ostream &, DeviceDataHistory &)

Is an utility function to easily print the contents of a DeviceDataHistory object. This function knows all types which could be inserted in a DeviceDataHistory object and print them accordingly. It also prints date and error stack in case the command returned an error.

```cpp
DeviceProxy *dev = new DeviceProxy("...");
int hist_depth = 4;
vector<DeviceDataHistory> *hist;
hist = dev->command_history("MyCommand", hist_depth);
for (int i = 0; i < hist_depth; i++)
{
    cout << (*hist)[i] << endl;
}
dele hist;
```

6.4 Tango::DeviceAttribute

This is the fundamental type for sending and receiving data to and from device attributes. The values can be inserted and extracted using the operators << and >> respectively and insert() for mixed data types. There are two ways to check if the extraction operator succeed:

1. By testing the extractor operators return value. All the extractors operator returns a boolean value set to false in case of problem.
2. By asking the DeviceAttribute object to throw exception in case of problem. By default, DeviceAttribute throws exception:

(a) when the user tries to extract data and the server reported an error when the attribute was read.
(b) When the user tries to extract data from an empty DeviceAttribute

6.4.1 Constructors

Many constructors have been written for this class. The following constructors exist:

1. The C++ basic constructors

(a) DeviceAttribute();
(b) DeviceAttribute(const DeviceAttribute&);

2. Constructors for scalar type with name as C++ string or "const char *

(a) DeviceAttribute(string &, bool);
(b) DeviceAttribute(string &, short);
(c) DeviceAttribute(string &, long);
(d) DeviceAttribute(string &, float);
(e) DeviceAttribute(string &, double);
(f) DeviceAttribute(string &, unsigned char);
(g) DeviceAttribute(string &, unsigned short);
(h) DeviceAttribute(string &, string &);
(i) DeviceAttribute(const char *, bool);
(j) DeviceAttribute(const char *, short);
(k) DeviceAttribute(const char *, long);
(l) DeviceAttribute(const char *, float);
(m) DeviceAttribute(const char *, double);
(n) DeviceAttribute(const char *, unsigned char);
(o) DeviceAttribute(const char *, unsigned short);
(p) DeviceAttribute(const char *, string &);

3. Constructors for C++ vector types (for spectrum attribute) with name as C++ string or "const char *

(a) DeviceAttribute(string &, vector<bool> &);
(b) DeviceAttribute(string &, vector<short> &);
(c) DeviceAttribute(string &, vector<long> &);
(d) DeviceAttribute(string &, vector<float> &);
(e) DeviceAttribute(string &, vector<double> &);
(f) DeviceAttribute(string &, vector<unsigned char> &);
(g) DeviceAttribute(string &, vector<unsigned short> &);
(h) DeviceAttribute(string &, vector<string> &);
(i) DeviceAttribute(const char *, vector<bool> &);
DeviceAttribute(const char *, vector<short> &);
DeviceAttribute(const char *, vector<long> &);
DeviceAttribute(const char *, vector<float> &);
DeviceAttribute(const char *, vector<double> &);
DeviceAttribute(const char *, vector<unsigned char> &);
DeviceAttribute(const char *, vector<unsigned short> &);
DeviceAttribute(const char *, vector<string> &);

4. Constructors for C++ vector types (for image attribute) with name as C++ string or "const char *". These constructors have two more parameters allowing the user to define the x and y image dimensions.

DeviceAttribute(string &, vector<bool> &, int, int);
DeviceAttribute(string &, vector<short> &, int, int);
DeviceAttribute(string &, vector<long> &, int, int);
DeviceAttribute(string &, vector<float> &, int, int);
DeviceAttribute(string &, vector<double> &, int, int);
DeviceAttribute(string &, vector<unsigned char> &, int, int);
DeviceAttribute(string &, vector<unsigned short> &, int, int);
DeviceAttribute(string &, vector<string> &, int, int);

6.4.2 Operators

Special care has been taken to avoid memory copy between the network layer and the user application. Nevertheless, C++ vector types are not the CORBA native type and one copy is unavoidable when using vectors. Using the native TANGO CORBA sequence types in most cases avoid any copy but needs some more care about memory usage.

- For insertion into DeviceAttribute instance from TANGO CORBA sequence pointers, the DeviceAttribute object takes ownership of the pointed to memory. This means that the pointed to memory will be freed when the DeviceAttribute object is destroyed or when another data is inserted into it.

- The insertion into DeviceAttribute instance from TANGO CORBA sequence reference copy the data into the DeviceAttribute object.

- For extraction into TANGO CORBA sequence types, the extraction method consumes the memory allocated to store the data and it is the caller responsibility to delete this memory.
As it has been done for constructors, a lot of insertors operator for classical C++ data types have been defined:

1. Insert operators for the following scalar C++ types:
   (a) bool
   (b) short
   (c) long
   (d) float
   (e) double
   (f) unsigned char
   (g) unsigned short
   (h) string

2. Insert operators for the following C++ vector types for spectrum attributes:
   (a) vector<bool>
   (b) vector<short>
   (c) vector<long>
   (d) vector<float>
   (e) vector<double>
   (f) vector<unsigned char>
   (g) vector<unsigned short>
   (h) vector<string>

3. Insert methods for the following C++ vector types for image attributes allowing the specification of the x and y image dimensions:
   (a) insert(vector<bool> &int, int)
   (b) insert(vector<short> &,int, int)
   (c) insert(vector<long> &,int, int)
   (d) insert(vector<float> &,int, int)
   (e) insert(vector<double> &,int, int)
   (f) insert(vector<unsigned char> &,int, int)
   (g) insert(vector<unsigned short> &,int, int)
   (h) insert(vector<string> &,int, int)

Extractor operators are specified for the following C++ basic types

1. Extract operators for the following scalar C++ types:
   (a) bool
   (b) short
   (c) long
   (d) float
   (e) double
   (f) unsigned char
(g) unsigned short
(h) string
(i) Tango::DevState

2. Extract operators for the following C++ vector types for spectrum and image attributes:

(a) vector<bool>
(b) vector<short>
(c) vector<long>
(d) vector<float>
(e) vector<double>
(f) vector<unsigned char>
(g) vector<unsigned short>
(h) vector<string>

Operators also exist for extracting some native TANGO CORBA sequence types. These can be useful for programmers who want to use the TANGO api internally in their device servers and do not want to convert from CORBA to C++ types.

1. Insert operators for spectrum attribute and for the following types by pointer:

(a) DevVarBooleanArray *
(b) DevVarShortArray *
(c) DevVarLongArray *
(d) DevVarFloatArray *
(e) DevVarDoubleArray *
(f) DevVarUCharArray *
(g) DevVarUShortArray *
(h) DevVarStringArray *

2. Insert operators for spectrum attribute and for the following types by reference:

(a) const DevVarBooleanArray &
(b) const DevVarShortArray &
(c) const DevVarLongArray &
(d) const DevVarFloatArray &
(e) const DevVarDoubleArray &
(f) const DevVarUCharArray &
(g) const DevVarUShortArray &
(h) const DevVarStringArray &

3. Insert methods for image attribute and pointers. These method allow the programmer to define the x and y image dimensions. The following methods are defined:

(a) insert(DevVarBooleanArray *, int, int )
(b) insert(DevVarShortArray *, int, int )
(c) insert(DevVarLongArray *, int, int )
(d) insert(DevVarFloatArray *, int , int )
(e) insert(DevVarDoubleArray *, int , int )
(f) insert(DevVarUCharArray *, int , int )
(g) insert(DevVarUShortArray *, int , int )
(h) insert(DevVarStringArray *, int , int )

4. Insert methods for image attribute and reference. These method allow the programmer to
define the x and y image dimensions. The following methods are defined:

(a) insert(const DevVarBooleanArray &, int , int )
(b) insert(const DevVarShortArray &, int , int )
(c) insert(const DevVarLongArray &, int , int )
(d) insert(const DevVarFloatArray &, int , int )
(e) insert(const DevVarDoubleArray &, int , int )
(f) insert(const DevVarUCharArray &, int , int )
(g) insert(const DevVarUShortArray &, int , int )
(h) insert(const DevVarStringArray &, int , int )

5. Extract operators for the following types:

(a) DevVarBooleanArray *
(b) DevVarShortArray *
(c) DevVarLongArray *
(d) DevVarFloatArray *
(e) DevVarDoubleArray *
(f) DevVarUCharArray *
(g) DevVarUShortArray *
(h) DevVarStringArray *

Here is an example of creating, inserting and extracting some DeviceAttribute types:

```
DeviceAttribute my_short, my_long, my_string;
DeviceAttribute my_float_vector, my_double_vector;
string a_string;
short a_short;
long a_long;
vector<float> a_float_vector;
vector<double> a_double_vector;
my_short << 100; // insert a short
my_short >> a_short; // extract a short
my_long << 1000; // insert a long
my_long >> a_long; // extract a long
my_string << string("estas lista a bailar el tango?"); // insert a string
my_string >> a_string; // extract a string
my_float_vector << a_float_vector // insert a vector of floats
my_float_vector >> a_float_vector; // extract a vector of floats
my_double_vector << a_double_vector; // insert a vector of doubles
my_double_vector >> a_double_vector; // extract a vector of doubles
```
/// Example of memory management with TANGO sequence types without memory leaks
///
for (int i = 0; i < 10; i++)
{
    DeviceAttribute da;
    DevVarLongArray *out;
    try
    {
        da = device->read_attribute("Attr");
        da >> out;
    }
    catch(DevFailed &e)
    {
        ....
    }
    cout << "Received value = " << (*out)[0];
    delete out;
}

Exception: WrongData if requested

6.4.3 bool DeviceAttribute::is_empty()

is_empty() is a boolean method which returns true or false depending on whether the DeviceAttribute object contains data or not. It can be used to test whether the DeviceAttribute has been initialized or not e.g.

    string parity;
    DeviceAttribute sl_parity = my_device->read_attribute("parity");
    if (!sl_parity.is_empty())
    {
        sl_parity >> parity;
    } else
    {
        cout << " no parity attribute defined for serial line !" << endl;
    }

Exception: WrongData if requested

6.4.4 void DeviceAttribute::exceptions(bitset<DeviceAttribute::numFlags>)

Is a method which allows the user to switch on/off exception throwing when trying to extract data from an empty DeviceAttribute object or with a wrong data type. The following flags are supported:

1. isempty_flag - throw a WrongData exception (reason= API_EmptyDeviceAttribute) if user tries to extract data from an empty DeviceAttribute object. By default, this flag is not set.
2. **wrongtype_flag** - throw a WrongData exception (reason = API_IncompatibleAttrArgumentType) if user tries to extract data with a type different than the type used for insertion. By default, this flag is not set.

3. **failed_flag** - throw an exception when the user try to extract data from the DeviceAttribute object and an error was reported by the server when the user try to read the attribute. The type of the exception thrown is the type of the error reported by the server. By default, this flag is set.

### 6.4.5 `bitset<DeviceAttribute::numFlags> exceptions()`

Return the whole exception flags.

### 6.4.6 `void DeviceAttribute::reset_exceptions(DeviceAttribute::except_flags fl)`

Reset one exception flag

### 6.4.7 `void DeviceAttribute::set_exceptions(DeviceAttribute::except_flags fl)`

Set one exception flag

The following is an example of how to use these exceptions related methods

```cpp
1   DeviceAttribute da;
2   bitset<DeviceAttribute::numFlags> bs = da.exceptions();
3   cout << "bs = " << bs << endl;
4   da.set_exceptions(DeviceAttribute::wrongtype_flag);
5   bs = da.exceptions();
6   cout << "bs = " << bs << endl;
```

### 6.4.8 `bool DeviceAttribute::has_failed()`

Returns a boolean set to true if the server report an error when the attribute was read.

### 6.4.9 `const DevErrorList &DeviceAttribute::get_err_stack()`

Returns the error stack reported by the server when the attribute was read.

The following is an example of the three available ways to get data out of a DeviceAttribute object.

```cpp
1   DeviceAttribute da;
2   vector<short> attr_data;
3   try
4   {
```
CHAPTER 6. THE TANGO C++ APPLICATION PROGRAMMER INTERFACE

```c++
  da = device->read_attribute("Attr");  
  da >> attr_data;
}
catch (DevFailed &e)
{
    ....
}
DeviceAttribute da;
vector<short> attr_data;
da.reset_exceptions(DeviceAttribute::failed_flag);
try
{
  da = device->read_attribute("Attr");
}
catch (DevFailed &e)
{
    ....
}
if (!da >> attr_data)
{
  DevErrorList &err = da.get_err_stack();
  ....
}
else
{
    ....
}
DeviceAttribute da;
vector<short> attr_data;
try
{
  da = device->read_attribute("Attr");
}
catch (DevFailed &e)
{
    ....
}
if (da.has_failed())
{
  DevErrorList &err = da.get_err_stack();
  ....
}
```
60     } else
61     {
62         da >> attr_data;
63     }

The first way is coded between lines 1 and 13. It uses the default behaviour of the DeviceAttribute object which is to throw an exception when the user try to extract data when the server reports an error when the attribute was read. The second way is coded between line 17 and 40. The DeviceAttribute object now does not throw "failed" exception any more and the return value of the extractor operator is checked. The third way is coded between line 43 and 63. In this case, the attribute data validity is checked before trying to extract them.

6.4.10 string &DeviceAttribute::get_name()

Returns the name of the attribute

6.4.11 void DeviceAttribute::set_name(string &)

Sets attribute name

6.4.12 void DeviceAttribute::set_name(const char *)

Sets attribute name

6.4.13 AttrQuality &DeviceAttribute::get_quality()

Returns the quality of the attribute: an enumerate type which can be one of {ATTR_VALID, ATTR_INVALID, ATTR_ALARM, ATTR_CHANGING or ATTR_WARNING}.

6.4.14 int DeviceAttribute::get_dim_x()

Returns the attribute read x dimension

6.4.15 int DeviceAttribute::get_dim_y()

Returns the attribute read y dimension

6.4.16 AttributeDimension DeviceAttribute::get_r_dimension()

Returns the attribute read dimension

6.4.17 AttributeDimension DeviceAttribute::get_w_dimension()

Returns the attribute write dimension

6.4.18 long DeviceAttribute::get_nb_read()

Returns the number of read values
6.4.19 long DeviceAttribute::get_nb_written()

Returns the number of written values. Here is an example of these last methods usage.

```cpp
DeviceAttribute da;
vector<short> attr_data;
try {
    da = device->read_attribute("Attr");
da >> attr_data;
}
catch (DevFailed &e) {
    ....
}
long read = da.get_nb_read();
long written = da.get_nb_written();
for (long i = 0; i < read; i++)
cout << "Read value " << i+1 << " = " << attr_data[i] << endl;
for (long j = 0; j < written; j++)
cout << "Last written value " << j+1 << " = " << attr_data[j + read] << endl;
```

6.4.20 TimeVal &DeviceAttribute::get_date()

Returns a reference to the time when the attribute was read in server

6.4.21 int DeviceAttribute::get_type()

Returns the type of the attribute data.

6.4.22 ostream &operator<<(ostream &, DeviceAttribute &)

Is an utility function to easily print the contents of a DeviceAttribute object. This function knows all types which could be inserted in a DeviceAttribute object and print them accordingly if the data are valid. It also prints the date returned within the attribute, the attribute name, the dim_x and dim_y attribute parameter and its quality factor.

```cpp
DeviceProxy *dev = new DeviceProxy("...");
DeviceAttribute attr;
attr = dev->read_attribute("MyAttribute");
cout << "Attribute returned: " << attr << endl;
```
6.5 Tango::DeviceAttributeHistory

This is the fundamental type for receiving data from device attribute polling buffers. This class inherits from the Tango::DeviceAttribute class. One instance of this class is created for each attribute result history. Within this class, you find the attribute result data or the exception parameters and a flag indicating if the attribute has failed when it was invoked by the device server polling thread. For history calls, it is not possible to return attribute error as exception. See chapter on Advanced Features for all details regarding device polling. On top of the methods inherited from the DeviceAttribute class, it offers the following methods.

6.5.1 ostream &operator<<(ostream &, DeviceAttributeHistory &)

Is an utility function to easily print the contents of a DeviceAttributeHistory object. This function knows all types which could be inserted in a DeviceAttributeHistory object and print them accordingly. It also prints date, attribute name, attribute dim_x and dim_y parameters, attribute quality factor and error stack in case the attribute returned an error.

```cpp
    DeviceProxy *dev = new DeviceProxy("...");
    int hist_depth = 4;
    vector<DeviceAttributeHistory> *hist;
    hist = dev->attribute_history("MyAttribute", hist_depth);
    for (int i = 0; i < hist_depth; i++)
    {
        cout << (*hist)[i] << endl;
    }
    delete hist;
```

6.6 Tango::AttributeProxy()

The high level object which provides the client with an easy-to-use interface to TANGO device attributes. AttributeProxy is a handle to the real Attribute (hence the name Proxy) and is not the real Attribute (of course). The AttributeProxy manages timeouts, stateless connections (new AttributeProxy() nearly always works), and reconnection if the device server is restarted.

6.6.1 Constructors

6.6.1.1 AttributeProxy::AttributeProxy(string &name)

Create an AttributeProxy to an attribute of the specified name. The constructor will connect to the TANGO database, query for the device to which the attribute belongs to network address and build a connection to this device. If the device to which the attribute belongs to is defined in the TANGO database but the device server is not running, AttributeProxy will try to build a connection every time the client tries to access the attribute. If an alias name is defined for the attribute, this alias name can be used to create the AttributeProxy instance. If a device name alias is defined for the device, it can be used instead of the three fields device name. If the device to which the attribute belongs to is not defined in the database, an exception is thrown. Examples :

```cpp
```
AttributeProxy *my_attr = new AttributeProxy("my/own/device/attr");
AttributeProxy *my_attr_bis = new AttributeProxy("attr_alias");
AttributeProxy *my_attr_ter = new AttributeProxy("dev_alias/attr");

See appendix on device/attribute naming for all details about Tango device or attribute naming syntax.
Exception: WrongNameSyntax, ConnectionFailed

6.6.1.2 AttributeProxy::AttributeProxy(const char *name)
Idem previous call

6.6.2 Miscellaneous methods
6.6.2.1 DevState AttributeProxy::state()
A method which returns the state of the device to which the attribute belongs to. This state is returned as a Tango::DevState type. Example:

```
dev_state = my_attr->state() << endl;
```

Exception: ConnectionFailed, CommunicationFailed

6.6.2.2 string AttributeProxy::status()
A method which return the status of the device to which the attribute belongs to. The status is returned as a string. Example:

```
cout << "device status" << my_attr->status() << endl;
```

Exception: ConnectionFailed, CommunicationFailed

6.6.2.3 int AttributeProxy::ping()
A method which sends a ping to the device to which the attribute belongs and returns the time elapsed in microseconds. Example:

```
cout << "device ping took " << my_device->ping() << " microseconds" << endl;
```

Exception: ConnectionFailed, CommunicationFailed

6.6.2.4 string AttributeProxy::name()
Returns the attribute name
6.6.2.5 DeviceProxy *get_device_proxy()

Returns the DeviceProxy instance used to communicate with the device to which the attributes belongs.

6.6.3 Synchronous related methods

6.6.3.1 AttributeInfo AttributeProxy::get_config()

Return the attribute configuration. AttributeInfo is a struct defined as follows:

```
typedef struct _AttributeInfo {
    string name;
    AttrWriteType writable;
    AttrDataFormat data_format;
    int data_type;
    int max_dim_x;
    int max_dim_y;
    string description;
    string label;
    string unit;
    string standard_unit;
    string display_unit;
    string format;
    string min_value;
    string max_value;
    string min_alarm;
    string max_alarm;
    string writable_attr_name;
    vector<string> extensions;
    Tango::DispLevel disp_level;
} AttributeInfo;
```

Exception: ConnectionFailed, CommunicationFailed, DevFailed from device

6.6.3.2 void AttributeProxy::set_config(AttributeInfo &)

Change the attribute configuration.

Exception: ConnectionFailed, CommunicationFailed, DevFailed from device

6.6.3.3 DeviceAttribute AttributeProxy::read()

Read the attribute. To extract the value you have to use the operator of the class DeviceAttribute which corresponds to the data type of the attribute. NOTE: There is no automatic type conversion from the attribute native type to user type e.g. if an attribute returns a short you cannot extract it as a double (this will return 0) you have to extract it as a short.

Exception: ConnectionFailed, CommunicationFailed, DevFailed from device
6.3.4 void AttributeProxy::write(DeviceAttribute&)

Write the attribute. To insert the value to write you have to use the operator of the class DeviceAttribute which corresponds to the data type of the attribute. NOTE There is no automatic type conversion from the user type to the attribute native type e.g. if an attribute expects a short you cannot insert it as a double (this will throw an exception) you have to insert it as a short.

Exceptions: ConnectionFailed, CommunicationFailed, DevFailed from device

6.3.5 vector<DeviceAttributeHistory> *AttributeProxy::history(int)

Retrieve attribute history from the attribute polling buffer. The argument is the wanted history depth. This method returns a vector of DeviceAttributeHistory types. This method allocates memory for the vector of DeviceAttributeHistory returned to the caller. It is the caller responsibility to delete this memory. Class DeviceAttributeHistory is detailed on chapter 6.5 See chapter on Advanced Feature for all details regarding polling.

```cpp
AttributeProxy attr = new AttributeProxy("my/own/device/Current");
vector<DeviceAttributeHistory> *hist;
hist = attr->history(5);
for (int i = 0; i < 5; i++)
{
    bool fail = (*hist)[i].has_failed();
    if (fail == false)
    {
        cout << "Attribute name = " << (*hist)[i].get_name() << endl;
        cout << "Attribute quality factor = " << (*hist)[i].get_quality() << endl;
        long value;
        (*hist)[i] >> value;
        cout << "Current = " << value << endl;
    }
    else
    {
        cout << "Attribute failed !" << endl;
        cout << "Error level 0 desc = " << ((*hist)[i].get_err_stack())[0].desc << endl;
    }
    cout << "Date = " << (*hist)[i].get_date().tv_sec << endl;
}
delete hist;
```

Exceptions: NonSupportedFeature, ConnectionFailed, CommunicationFailed, DevFailed from device

6.4 Asynchronous methods

6.4.1 long AttributeProxy::read_asynch()

Read the attribute asynchronously (polling model). This call returns an asynchronous call identifier which is needed to get the attribute value.

Exceptions: ConnectionFailed
6.6.4.2 DeviceAttribute *AttributeProxy::read_reply(long id)

Check if the answer of an asynchronous read is arrived (polling model). id is the asynchronous call identifier. If the reply is arrived and if it is a valid reply, it is returned to the caller in a DeviceAttribute object. If the reply is an exception, it is re-thrown by this call. An exception is also thrown in case of the reply is not yet arrived. To extract attribute value, you have to use the operator of the class DeviceAttribute which corresponds to the data type of the attribute. 

NOTE: There is no automatic type conversion from the attribute native type to user type e.g. if an attribute returns a short you cannot extract it as a double, you have to extract it as a short. Memory has been allocated for the DeviceAttribute object returned to the caller. This is the caller responsibility to delete this memory.

Exception: AsynCall, AsynReplyNotArrived, CommunicationFailed, DevFailed from device

6.6.4.3 DeviceAttribute *AttributeProxy::read_reply(long id, long timeout)

Check if the answer of an asynchronous read is arrived (polling model). id is the asynchronous call identifier. If the reply is arrived and if it is a valid reply, it is returned to the caller in a DeviceAttribute object. If the reply is an exception, it is re-thrown by this call. If the reply is not yet arrived, the call will wait (blocking the process) for the time specified in timeout. If after timeout milliseconds, the reply is still not there, an exception is thrown. If timeout is set to 0, the call waits until the reply arrived. To extract attribute value, you have to use the operator of the class DeviceAttribute which corresponds to the data type of the attribute. 

NOTE: There is no automatic type conversion from the attribute native type to user type e.g. if an attribute returns a short you cannot extract it as a double, you have to extract it as a short. Memory has been allocated for the DeviceAttribute object returned to the caller. This is the caller responsibility to delete this memory.

Exception: AsynCall, AsynReplyNotArrived, CommunicationFailed, DevFailed from device

6.6.4.4 long AttributeProxy::write_async(DeviceAttribute &argin)

Write the attribute asynchronously (polling model). To insert the value to write you have to use the operator of the class DeviceAttribute which corresponds to the data type of the attribute. 

NOTE: There is no automatic type conversion from the user type to the attribute native type e.g. if an attribute expects a short you cannot insert it as a double (this will throw an exception) you have to insert it as a short. This call returns an asynchronous call identifier which is needed to get the server reply.

Exception: ConnectionFailed

6.6.4.5 void AttributeProxy::write_reply(long id)

Check if the answer of an asynchronous write is arrived (polling model). id is the asynchronous call identifier. If the reply is arrived and if it is a valid reply, the call returned. If the reply is an exception, it is re-thrown by this call. An exception is also thrown in case of the reply is not yet arrived.

Exception: AsynCall, AsynReplyNotArrived, CommunicationFailed, DevFailed from device

6.6.4.6 void AttributeProxy::write_reply(long id, long timeout)

Check if the answer of an asynchronous write is arrived (polling model). id is the asynchronous call identifier. If the reply is arrived and if it is a valid reply, the call returned. If the reply is an exception, it is re-thrown by this call. If the reply is not yet arrived, the call will wait (blocking the process) for the time specified in timeout. If after timeout milliseconds, the reply is still not there, an exception is thrown. If timeout is set to 0, the call waits until the reply arrived.

Exception: AsynCall, AsynReplyNotArrived, CommunicationFailed, DevFailed from device
6.6.4.7 void AttributeProxy::read_asynch(CallBack &cb)
Read the attribute asynchronously using the callback model. The argument is a reference to a
callback object. This callback object should be an instance of a user class inheriting from the
Tango::CallBack class with the attr_read() method overloaded.

Exception: ConnectionFailed

6.6.4.8 void AttributeProxy::write_asynch(DeviceAttribute &argin, CallBack &cb)
Write the attribute asynchronously using the callback model. The argument is a reference to a
callback object. This callback object should be an instance of a user class inheriting from the
Tango::CallBack class with the attr_written() method overloaded.

Exception: ConnectionFailed

6.6.5 Polling related methods
6.6.5.1 bool AttributeProxy::is_polled()
Returns true if the attribute is polled. Otherwise, returns false.

6.6.5.2 int AttributeProxy::get_poll_period()
Returns the attribute polling period in mS. If the attribute is not polled, it returns 0.

6.6.5.3 void AttributeProxy::poll(int period)
Add the attribute to the list of polled attributes. The polling period is specified by "period" (in
mS). If the attribute is already polled, this method will update the polling period according to
"period".

6.6.5.4 void AttributeProxy::stop_poll()
Remove attribute from the list of polled attributes.

6.6.6 Event related methods
6.6.6.1 int AttributeProxy::subscribe_event(EventType event, CallBack *cb, const
vector<string> &filters)
The client call to subscribe to an event. The client implements a callback method which is triggered
when the event is received either by polling or a dedicated thread. Filtering is done based on the
reason specified and the event type. For example when reading the state and the reason specified
is "change" the event will be fired only when the state changes. Events consist of an attribute
name and the event reason. A standard set of reasons are implemented by the system, additional
device specific reasons can be implemented by device servers programmers.

The *event* parameter is the event reason and must be on the enumerated values:

- Tango::CHANGE_EVENT
- Tango::PERIODIC_EVENT
- Tango::QUALITY_EVENT
- Tango::ARCHIVE_EVENT
6.6.6.2 `void AttributeProxy::unsubscribe_event(int event_id)`

Unsubscribe a client from receiving the event specified by `event_id`. `event_id` is the event identifier returned by the `AttributeProxy::subscribe_event()` method.

`Exception: EventSystemFailed`

6.6.7 Property related methods

6.6.7.1 `void AttributeProxy::get_property (string&, DbData&)`  

Get a single property for the attribute. The property to get is specified as a string. Refer to `DbDevice::get_property()` and `DbData` sections below for details on the `DbData` type.

`Exception: NonDbDevice, ConnectionFailed (with database), CommunicationFailed (with database), DevFailed from database device`

6.6.7.2 `void AttributeProxy::get_property (vector<string>&, DbData&)`  

Get a list of properties for the attribute. The properties to get are specified as a vector of strings. Refer to `DbDevice::get_property()` and `DbData` sections below for details on the `DbData` type.

`Exception: NonDbDevice, ConnectionFailed (with database), CommunicationFailed (with database), DevFailed from database device`

6.6.7.3 `void AttributeProxy::get_property(DbData&)`  

Get property(ies) for the attribute. Properties to get are specified using the `DbData` type. Refer to `DbDevice::get_property()` and `DbData` sections below for details.

`Exception: NonDbDevice, ConnectionFailed (with database), CommunicationFailed (with database), DevFailed from database device`

6.6.7.4 `void AttributeProxy::put_property(DbData&)`  

Put property(ies) for an attribute. Properties to put are specified using the `DbData` type. Refer to `DbDevice::put_property()` and `DbData` sections below for details.

`Exception: NonDbDevice, ConnectionFailed (with database), CommunicationFailed (with database), DevFailed from database device`

6.6.7.5 `void AttributeProxy::delete_property (string&, DbData&)`  

Delete a single property for an attribute. The property to delete is specified as a string. Refer to `DbDevice::delete_property()` and `DbData` sections below for details on the `DbData` type.

`Exception: NonDbDevice, ConnectionFailed (with database), CommunicationFailed (with database), DevFailed from database device`

6.6.7.6 `void AttributeProxy::delete_property (vector<string>&, DbData&)`  

Delete a list of properties for an attribute. The properties to delete are specified as a vector of strings. Refer to `DbDevice::get_property()` and `DbData` sections below for details on the `DbData` type.

`Exception: NonDbDevice, ConnectionFailed (with database), CommunicationFailed (with database), DevFailed from database device`
6.6.7.7  **void AttributeProxy::delete_property(DbData&)**

Delete property(ies) for an attribute. Properties to delete are specified using the DbData type.
Refer to DbDevice::get_property() and DbData sections below for details.

*Exception: NonDbDevice, ConnectionFailed (with database), CommunicationFailed (with database),
DevFailed from database device*

6.7  **Tango::ApiUtil**

This class is a singleton. Therefore, it is not necessary to create it. It will be automatically done.
A static method allows a user to retrieve the instance

6.7.1  **static ApiUtil *ApiUtil::instance()**

Return the ApiUtil singleton instance.

6.7.2  **static void ApiUtil::cleanup()**

Destroy the ApiUtil singleton instance.

6.7.3  **long ApiUtil::pending_asynch_call(asyn_req_type req)**

Return number of asynchronous pending requests (any device). The input parameter is an enum-
eration with three values which are:

- POLLING : Return only polling model asynchronous request number
- CALL_BACK : Return only callback model asynchronous request number
- ALLASYNCH: Return all asynchronous request number

*Exception: None*

6.7.4  **void ApiUtil::get_asynch_replies()**

Fire callback methods for all (any device) asynchronous requests (command and attribute) with
already arrived replied. Returns immediately if there is no replies already arrived or if there is no
asynchronous requests.

*Exception: None, all errors are reported using the err and errors fields of the parameter passed
to the callback method. See chapter 6.8 for details.*

6.7.5  **void ApiUtil::get_asynch_replies(long timeout)**

Fire callback methods for all (any device) asynchronous requests (command and attributes) with
already arrived replied. Wait and block the caller for timeout milliseconds if they are some device
asynchronous requests which are not yet arrived. Returns immediately if there is no asynchronous
request. If timeout is set to 0, the call waits until all the asynchronous requests sent has received
a reply.

*Exception: AsyncReplyNotArrived. All other errors are reported using the err and errors fields
of the object passed to the callback methods. See chapter 6.8 for details.*
6.7.6  void ApiUtil::set_asynch_cb_sub_model(cb_sub_model model)
Set the asynchronous callback sub-model between the pull and push sub-model. See chapter 4.4
to read the definition of these sub-model. The cb_sub_model data type is an enumeration with
two values which are :
PUSH_CALLBACK : The push sub-model
PULL_CALLBACK : The pull sub-model
By default, all Tango client using asynchronous callback model are in pull sub-model. This call
must be used to switch to the push sub-model. NOTE that in push sub-model, a separate thread
is spawned to deal with server replies.
   Exception: None
6.7.7 cb_sub_model ApiUtil::get_asynch_cb_sub_model()
Get the asynchronous callback sub-model.
   Exception: None
6.8 Asynchronous callback related classes
6.8.1 Tango::CallBack
6.8.1.1 void CallBack::cmdEnded(CmdDoneEvent *event)
This method is defined as being empty and must be overloaded by the user when the asynchronous
callback model is used. This is the method which will be executed when the server reply from a
command_inout is received in both push and pull sub-mode.
6.8.1.2 void CallBack::attrRead(AttrReadEvent *event)
This method is defined as being empty and must be overloaded by the user when the asynchronous
callback model is used. This is the method which will be executed when the server reply from a
read_attribute(s) is received in both push and pull sub-mode.
6.8.1.3 void CallBack::attrWritten(AttrWrittenEvent *event)
This method is defined as being empty and must be overloaded by the user when the asynchronous
callback model is used. This is the method which will be executed when the server reply from a
write_attribute(s) is received in both push and pull sub-mode.
6.8.1.4 void CallBack::pushEvent(EventData *event)
This method is defined as being empty and must be overloaded by the user when events are used.
This is the method which will be executed when the server send event(s) to the client.
6.8.2 Tango::CmdDoneEvent
This class is used to pass data to the callback method in asynchronous callback model for command
execution. It contains the following public field
device : The DeviceProxy object on which the call was executed (Tango::DeviceProxy *)
cmd_name : The command name (string &)
argout : The command argout (DeviceData &)
CHAPTER 6. THE TANGO C++ APPLICATION PROGRAMMER INTERFACE

```cpp
err : A boolean flag set to true if the command failed. False otherwise (bool)
errors : The error stack (DevErrorList &)

6.8.3 Tango::AttrReadEvent
This class is used to pass data to the callback method in asynchronous callback model for read_attribute(s) execution. It contains the following public field

device : The DeviceProxy object on which the call was executed (Tango::DeviceProxy *)
attr_names : The attribute name list (vector< string > &)
argout : The attribute data (vector<DeviceAttribute> *)
err : A boolean flag set to true if the request failed. False otherwise (bool)
errors : The error stack (DevErrorList &)

To extract attribute value(s), you have to use the operator of the class DeviceAttribute which corresponds to the data type of the attribute. NOTE: There is no automatic type conversion from the attribute native type to user type e.g. if an attribute returns a short you cannot extract it as a double, you have to extract it as a short. Memory has been allocated for the vector of DeviceAttribute objects passed to the caller. This is the caller responsibility to delete this memory.

6.8.4 Tango::AttrWrittenEvent
This class is used to pass data to the callback method in asynchronous callback model for write_attribute(s) execution. It contains the following public field

device : The DeviceProxy object on which the call was executed (Tango::DeviceProxy *)
attr_names : The attribute name list (vector< string > &)
err : A boolean flag set to true if the request failed. False otherwise (bool)
errors : The error stack (DevErrorList &)

6.8.5 Tango::EventData
This class is used to pass data to the callback method when an event is sent to the client. It contains the following public field

device : The DeviceProxy object on which the call was executed (Tango::DeviceProxy *)
attr_name : The attribute name (std::string &)
event : The event name (std::string &)
attr_value : The attribute data (DeviceAttribute *)
err : A boolean flag set to true if the request failed. False otherwise (bool)
errors : The error stack (DevErrorList &)

To extract attribute value(s), you have to use the operator of the class DeviceAttribute which corresponds to the data type of the attribute. NOTE: There is no automatic type conversion from the attribute native type to user type e.g. if an attribute returns a short you cannot extract it as a double, you have to extract it as a short. Memory has been allocated for the vector of DeviceAttribute objects passed to the caller. This is the caller responsibility to delete this memory.
```
6.9 Tango::Group

6.9.1 Constructor and Destructor

6.9.1.1 Group::Group (const std::string& name)

Instantiate an empty group. The group name allows retrieving a sub-group in the hierarchy.

See also: Group::~Group(), Group::get_group().

6.9.1.2 Group::~Group ()

Delete a group and all its elements.

Be aware that a group always gets the ownership of its children and deletes them when it is itself deleted. Therefore, never try to delete a Group (respectively a DeviceProxy) returned by a call to Tango::Group::get_group() (respectively to Tango::Group::get_device()). Use the Tango::Group::remove() method instead.

See also: Group::Group(), Group::remove(), Group::remove_all().

6.9.2 Group Management Related Methods

6.9.2.1 void Group::add (Group* group)

Attaches a (sub)group.

Be aware that a group always gets the ownership of its children and deletes them when it is itself deleted. Therefore, never try to delete a Group attached to a Group. Use the Group::remove() method instead.

This method does nothing if the specified group if already attached (i.e. it is silently ignored).

See also: all other forms of Group::add().

6.9.2.2 void Group::add (const std::string& pattern)

Attaches any device which name matches the specified pattern.

The pattern parameter can be a simple device name or a device name pattern (e.g. domain_*/
family/member_*)

This method first asks the Tango database the list of device names matching the pattern.
Devices are then attached to the group in the order in which they are returned by the database.

Any device already present in the hierarchy (i.e. a device belonging to the group or to one of
its subgroups) is silently ignored.

See also: all other forms of Group::add().

6.9.2.3 void Group::add (const std::vector<std::string>& patterns)

Attaches any device which name matches one of the specified patterns.

The patterns parameter can be an array of device names and/or device name patterns.

This method first asks the Tango database the list of device names matching one the patterns.
Devices are then attached to the group in the order in which they are returned by the database.

Any device already present in the hierarchy (i.e. a device belonging to the group or to one of
its subgroups), is silently ignored.

See also: all other forms of Group::add().

6.9.2.4 void Group::remove (const std::string& pattern, bool fwd = true)

Removes any group or device which name matches the specified pattern.

The pattern parameter can be a group name, a device name or a device name pattern (e.g
domain_*/family/member_*)

Since we can have groups with the same name in the hierarchy, a group name can be fully
qualified to specify which group should be removed. Considering the following group:
A call to `gauges->remove("penning")` will remove any group named "penning" in the hierarchy while `gauges->remove("gauges.cell-02 penning")` will only remove the specified group.

If `fwd` is set to true (the default), the remove request is also forwarded to subgroups. Otherwise, it is only applied to the local set of elements. For instance, the following code remove any stepper motor in the hierarchy:

```cpp
root_group->remove("*/stepper_motor/*");
```

See also: all other forms of `Group::remove()`.

### 6.9.2.5 void Group::remove (const std::vector<std::string>& patterns, bool fwd = true)

Removes any group or device which name matches the specified patterns.

The `patterns` parameter can be an array of group names and/or device names and/or device name patterns.

Since we can have groups with the same name in the hierarchy, a group name can be fully qualified to specify which group should be removed. See previous method for details.

If `fwd` is set to true (the default), the remove request is also forwarded to subgroups. Otherwise, it is only applied to the local set of elements.

See also: all other forms of `Group::remove()`.

### 6.9.2.6 void Group::remove_all (void)

Removes all elements in the group. After such a call, the group is empty.

See also: all forms of `Group::remove()`.

### 6.9.2.7 bool Group::contains (const std::string& pattern, bool fwd = true)

Returns true if the hierarchy contains groups and/or devices which name matches the specified `pattern`. Returns false otherwise.

The pattern can be a fully qualified or simple group name, a device name or a device name pattern.

If `fwd` is set to true (the default), the request is also forwarded to subgroups. Otherwise, it is only applied to the local set of elements.

See also: `Group::get_device()`, `Group::get_group()`.
6.9.2.8 DeviceProxy* Group::get_device (const std::string& device_name)

Returns a reference to the specified device or NULL if there is no device by that name in the
group. This method may throw an exception in case the specified device belongs to the group but
can’t be reached (not registered, down...). See example below. See also the Tango::DeviceProxy
class documentation for details.

```cpp
try
{
    Tango::DeviceProxy *dp = g->get_device("my/device/01");
    if (dp == 0)
    {
        // my/device/01 does not belong to the group
    }
    catch (const Tango::DevFailed &df)
    {
        // my/device/01 belongs to the group but can't be reached
    }
```

The request is systematically forwarded to subgroups (i.e. if no device named device_name
could be found in the local set of devices, the request is forwarded to subgroups).

Be aware that a group always gets the ownership of its children and deletes them when it is
itself deleted. Therefore, never try to delete a DeviceProxy returned by the Group::get_device() method. Use the Tango::Group::remove() method instead.

See also: other form of Group::get_device(), Group::get_size(), Group::get_group(), Group::contains().

6.9.2.9 DeviceProxy* Group::get_device (long idx)

Returns a reference to the "idx-th" device in the hierarchy or NULL if the hierarchy contains less
than "idx" devices. This method may throw an exception in case the specified device belongs
to the group but can’t be reached (not registered, down...). See previous example. See also the
Tango::DeviceProxy class documentation for details.

The request is systematically forwarded to subgroups (i.e. if the local set of devices contains
less than "idx" devices, the request is forwarded to subgroups).

Be aware that a group always gets the ownership of its children and deletes them when it is
itself deleted. Therefore, never try to delete a DeviceProxy returned by the Group::get_device() method. Use the Tango::Group::remove() method instead.

See also: other form of Group::get_device(), Group::get_size(), Group::get_group(), Group::contains().

6.9.2.10 DeviceProxy* Group::operator[] (long i)

Returns a reference to the "idx-th" device in the hierarchy or NULL if the hierarchy contains less
than "idx" devices. See the Tango::DeviceProxy class documentation for details.

The request is systematically forwarded to subgroups (i.e. if the local set of devices contains
less than "idx" devices, the request is forwarded to subgroups).

Be aware that a group always gets the ownership of its children and deletes them when it is
itself deleted. Therefore, never try to delete a DeviceProxy returned by the Group::get_device() method. Use the Tango::Group::remove() method instead.

See also: other form of Group::get_device(), Group::get_size(), Group::get_group(), Group::contains().
6.9.2.11 Group* Group::get_group (const std::string& group_name)

Returns a reference to the specified group or NULL if there is no group by that name. The
	group_name can be a fully qualified name.

Considering the following group:

-> gauges
  |--> cell-01
  |   |--> penning
  |   |   |--> ...
  |--> pirani
  |   |--> ...
  |--> cell-02
  |   |--> penning
  |   |   |--> ...
  |--> pirani
  |   |--> ...
  |--> cell-03
  |   |--> ...
  |   |--> ...

A call to gauges->get_group("penning") returns the first group named "penning" in the hierar-
chy (i.e. gauges.cell-01.penning) while gauges->get_group("gauges.cell-02.penning") returns the
specified group.

The request is systematically forwarded to subgroups (i.e. if no group named group_name
could be found in the local set of elements, the request is forwarded to subgroups).

Be aware that a group always gets the ownership of its children and deletes them when it is
itself deleted. Therefore, never try to delete a Group returned by the Group::get_group() method.

See also: Group::get_device(), Group::contains().

6.9.2.12 long Group::get_size (bool fwd = true)

Return the number of devices in the hierarchy (respectively the number of device in the group) if
the forward option is set to true (respectively set to false).

6.9.2.13 std::vector< std::string> Group::get_device_list (bool fwd = true)

Returns the list of devices currently in the hierarchy.

If fwd is set to true (the default) the request is forwarded to subgroups. Otherwise, it is only
applied to the local set of devices.

Considering the following hierarchy:

   g2->add("my/device/04"); g2->add("my/device/05");
   g4->add("my/device/08"); g4->add("my/device/09");

   g3->add("my/device/06");
g3->addg(g4);
   g3->add("my/device/07");

   gl->add("my/device/01");
gl->add(g2);
gl->add("my/device/03");
g1->add(g3);
g1->add("my/device/02");

The returned vector content depends on the value of the forward option. If set to true, the results will be organized as follows:

```cpp
std::vector<std::string> dl = g1->get_device_list(true);
```

- `dl[0]` contains "my/device/01" which belongs to g1
- `dl[1]` contains "my/device/04" which belongs to g1.g2
- `dl[2]` contains "my/device/05" which belongs to g1.g2
- `dl[3]` contains "my/device/03" which belongs to g1
- `dl[4]` contains "my/device/06" which belongs to g1.g3
- `dl[5]` contains "my/device/08" which belongs to g1.g3.g4
- `dl[6]` contains "my/device/09" which belongs to g1.g3.g4
- `dl[7]` contains "my/device/07" which belongs to g1.g3
- `dl[8]` contains "my/device/02" which belongs to g1

If the forward option is set to false, the results are:

```cpp
std::vector<std::string> dl = g1->get_device_list(false);
```

- `dl[0]` contains "my/device/01" which belongs to g1
- `dl[1]` contains "my/device/03" which belongs to g1
- `dl[2]` contains "my/device/02" which belongs to g1

6.9.3  "A la" DeviceProxy Methods

6.9.3.1  bool Group::ping (bool fwd = true)

Ping all devices in a group. This method returns true if all devices in the group are alive, false otherwise.

If `fwd` is set to true (the default), the request is also forwarded to subgroups. Otherwise, it is only applied to the local set of devices.

6.9.3.2  GroupCmdReplyList Group::command_inout (const std::string& c, bool fwd = true)

Executes a Tango command on a group. This method is synchronous and does not return until replies are obtained or timeouts occurred.

The parameter `c` is the name of the command.

If `fwd` is set to true (the default), the request is also forwarded to subgroups. Otherwise, it is only applied to the local set of devices.

Command results are returned in a GroupCmdReplyList. See Obtaining command result for details (4.6.3.1). See also Case 1 of executing a command (4.6.3.2) for an example.

6.9.3.3  GroupCmdReplyList Group::command_inout (const std::string& c, const DeviceData& d, bool fwd = true)

Executes a Tango command on each device in the group. This method is synchronous and does not return until replies are obtained or timeouts occurred.

The parameter `c` is the name of the command.

The second parameter `d` is a Tango generic container for command carrying the command argument. See the Tango::DeviceData documentation.

If `fwd` is set to true (the default), the request is also forwarded to subgroups. Otherwise, it is only applied to the local set of devices.

Command results are returned in a GroupCmdReplyList. See Obtaining command results (4.6.3.1) for details. See also Case 2 of executing a command (4.6.3.4) for an example.
6.9.3.4  template<typename T> GroupCmdReplyList Group::command_inout (const std::string& c, const std::vector<T>& d, bool fwd = true)

Executes a Tango command on each device in the group. This method is synchronous and does not return until replies are obtained or timeouts occurred.

This implementation of command_inout allows passing a specific input argument to each device in the group. In order to use this form of command_inout, the user must have an "a priori" and "perfect" knowledge of the devices order in the group.

The parameter c is the name of the command.

The std::vector d contains a specific argument value for each device in the group. Since this method is a template, d is able to contain any Tango command argument type. Its size must equal Group::get_size(fwd). Otherwise, an exception is thrown. The order of the argument values must follow the order of the devices in the group (d[0] => 1st device, d[1] => 2nd device and so on).

If fwd is set to true (the default), the request is also forwarded to subgroups. Otherwise, it is only applied to the local set of devices.

Command results are returned in a GroupCmdReplyList. See Obtaining command results (4.6.3.1) for details. See also Case 3 of executing a command (4.6.3.5) for an example of this special form of command_inout.

6.9.3.5  long Group::command_inout_asynch (const std::string& c, bool fgt = false, bool fwd = true, long rsv = -1)

Executes a Tango command on each device in the group asynchronously. The method sends the request to all devices and returns immediately. Pass the returned request id to Group::command_inout_reply() to obtain the results.

The parameter c is the name of the command.

The parameter fgt is a fire and forget flag. If set to true, it means that no reply is expected (i.e. the caller does not care about it and will not even try to get it). A false default value is provided.

If the parameter fwd is set to true (the default) request is forwarded to subgroups. Otherwise, it is only applied to the local set of devices.

Finally, rsv is reserved for internal purpose and should not be modify. This parameter may disappear in a near future.

See Case 1 of Executing a command (4.6.3.2) for an example.

6.9.3.6  long Group::command_inout_asynch (const std::string& c, const DeviceData& d, bool fgt = false, bool fwd = true, long rsv = -1)

Executes a Tango command on each device in the group asynchronously. The method sends the request to all devices and returns immediately. Pass the returned request id to Group::command_inout_reply() to obtain the results.

The parameter c is the name of the command.

The second parameter d is a Tango generic container for command carrying the command argument. See the Tango::DeviceData documentation for details.

The parameter fgt is a fire and forget flag. If set to true, it means that no reply is expected (i.e. the caller does not care about it and will not even try to get it). A false default value is provided.

If the parameter fwd is set to true (the default) request is forwarded to subgroups. Otherwise, it is only applied to the local set of devices.

Finally, rsv is reserved for internal purpose and should not be modify. This parameter may disappear in a near future.

See Case 2 of Executing a command (4.6.3.4) for an example.
6.9.3.7 long Group::command_inout_async (const std::string & c, const std::vector<T> & d, fgt = false, bool fwdf = true)

Executes a Tango command on each device in the group asynchronously. The method sends the request to all devices and returns immediately. Pass the returned request id to Group::command_inout_reply to obtain the results.

This implementation of command_inout allows passing a specific input argument to each device in the group. In order to use this form of command_inout_async, the user must have an "a priori" and "perfect" knowledge of the devices order in the group.

The parameter c is the name of the command.

The std::vector d contains a specific argument value for each device in the group. d is able to contain any Tango command argument type. Its size must equal Group::get_size(fwdf). Otherwise, an exception is thrown. The order of the argument values must follows the order of the devices in the group (d[0] => 1st device, d[1] => 2nd device and so on).

The parameter fgt is a fire and forget flag. If set to true, it means that no reply is expected (i.e. the caller does not care about it and will not even try to get it). A false default value is provided.

If fwdf is set to true (the default), the request is also forwarded to subgroups. Otherwise, it is only applied to the local set of devices.

See Case 3 of Executing a command (4.6.3.5) for an example of this special form of command_inout.

6.9.3.8 GroupCmdReplyList Group::command_inout_reply (long req_id, long timeout_ms = 0)

Returns the results of an asynchronous command.

The first parameter req_id is a request identifier previously returned by one of the command_inout_async methods.

For each device in the hierarchy, if the command result is not yet available, command_inout_reply waits timeout_ms milliseconds before throwing an exception. This exception will be part of the global reply. If timeout_ms is set to 0, command_inout_reply waits "indefinitely".

Command results are returned in a GroupCmdReplyList. See Obtaining command results (4.6.3.1) for details.

6.9.3.9 GroupAttrReplyList Group::read_attribute (const std::string & a, bool fwdf = true)

Reads an attribute on each device in the group. This method is synchronous and does not return until replies are obtained or timeouts occurred.

The parameter a is the name of the attribute to read.

If fwdf is set to true (the default) request is forwarded to subgroups. Otherwise, it is only applied to the local set of devices.

Attribute values are returned in a GroupAttrReplyList. See Obtaining attribute values (4.6.4.1) for details. See also Reading an attribute (4.6.4) for an example.

6.9.3.10 long Group::read_attribute_async (const std::string & a, bool fwdf = true, long rsv = -1)

Reads an attribute on each device in the group asynchronously. The method sends the request to all devices and returns immediately. Pass the returned request id to Group::read_attribute_reply() to obtain the results.

The parameter a is the name of the attribute to read.

If fwdf is set to true (the default) request is forwarded to subgroups. Otherwise, it is only applied to the local set of devices.
CHAPTER 6. THE TANGO C++ APPLICATION PROGRAMMER INTERFACE

The last parameter (rsv) is reserved for internal purpose and should not be modify. It may disappear in a near future.

See Reading an attribute (4.6.4) for an example.

6.9.3.11 GroupAttrReplyList Group::read_attribute_reply (long req_id, long timeout_ms = 0)

Returns the results of an asynchronous attribute reading.

The first parameter req_id is a request identifier previously returned by read_attribute_asynch.

For each device in the hierarchy, if the attribute value is not yet available, read_attribute_reply
wait timeout_ms milliseconds before throwing an exception. This exception will be part of the
global reply. If timeout_ms is set to 0, read_attribute_reply waits "indefinitely"

Replies are returned in a GroupAttrReplyList. See Obtaining attribute values (4.6.4.1) for
details.

6.9.3.12 GroupReplyList Group::write_attribute (const DeviceAttribute& d, bool fwd = true)

Writes an attribute on each device in the group. This method is synchronous and does not return
until acknowledgements are obtained or timeouts occurred.

The first parameter d is a Tango generic container for attribute carrying both the attribute
name and the name. See the Tango::DeviceAttribute documentation for details.

If fwd is set to true (the default) request is forwarded to subgroups. Otherwise, it is only
applied to the local set of devices.

Acknowledgements are returned in a GroupReplyList. See Obtaining acknowledgements (4.6.5.1)
for details. See also Case 1 of Writing an attribute (4.6.5.2) for an example.

6.9.3.13 GroupReplyList Group::write_attribute (const std::string& a, const std::vector<T>&
d, bool fwd = true)

Writes an attribute on each device in the group. This method is synchronous and does not return
until replies are obtained or timeouts occurred.

This implementation of write_attribute allows writing a specific value to each device in the
group. In order to use this form of write_attribute, the user must have an "a priori" and "perfect"
knowledge of the devices order in the group.

The parameter a is the name of the attribute.

The std::vector d contains a specific value for each device in the group. Since this method is a
template, d is able to contain any Tango attribute type. Its size must equal Group::get_size(fwd).
Otherwise, an exception is thrown. The order of the attribute values must follows the order of the
devices in the group (d[0] => 1st device, d[1] => 2nd device and so on).

If fwd is set to true (the default) request is forwarded to subgroups. Otherwise, it is only
applied to the local set of devices.

Acknowledgements are returned in a GroupReplyList. See Obtaining acknowledgements (4.6.5.1)
for details. See also Case 2 of Writing an attribute (4.6.5.3) for an example.

6.9.3.14 long Group::write_attribute_asynch (const DeviceAttribute& d, bool fwd
= true, long rsv = -1)

Writes an attribute on each device in the group asynchronously. The method sends the request to
all devices and returns immediately. Pass the returned request id to Group::write_attribute_reply()
to obtain the acknowledgements.

The first parameter d is a Tango generic container for attribute carrying both the attribute
name and the name. See the Tango::DeviceAttribute documentation for details.

If fwd is set to true (the default) request is forwarded to subgroups. Otherwise, it is only
applied to the local set of devices.
The last parameter rsv is reserved for internal purpose and should not be modify. It may disappear in a near future.

See Case 1 of Writing an attribute (4.6.5.2) for an example.

6.9.3.15 long Group::write_attribute_async (const std::string& a, const std::vector<T>& d, bool fwd = true)

Writes an attribute on each device in the group asynchronously. The method sends the request to all devices and returns immediately. Pass the returned request id to Group::write_attribute_reply() to obtain the acknowledgements.

This implementation of write_attribute_async allows writing a specific value to each device in the group. In order to use this form of write_attribute_async, the user must have an "a priori" and "perfect" knowledge of the devices order in the group.

The parameter a is the name of the attribute.

The std::vector d contains a specific value for each device in the group. Since this method is a template, d is able to contain any Tango attribute type. Its size must equal Group::get_size(fwd).

Otherwise, an exception is thrown. The order of the attribute values must follows the order of the devices in the group (d[0] => 1st device, d[1] => 2nd device and so on).

If fwd is set to true (the default) request is forwarded to subgroups. Otherwise, it is only applied to the local set of devices.

See Case2 of Writing an attribute (4.6.5.3) for an example.

6.9.3.16 GroupReplyList Group::write_attribute_reply (long req_id, long timeout_ms = 0)

Returns the acknowledgements of an asynchronous attribute writing.

The first parameter req_id is a request identifier previously returned by one of the write_attribute_async implementation.

For each device in the hierarchy, if the acknowledgement is not yet available, write_attribute_reply wait timeout_ms milliseconds before throwing an exception. This exception will be part of the global reply. If timeout_ms is set to 0, write_attribute_reply waits "indefinitely".

Acknowledgements are returned in a GroupReplyList. See Obtaining acknowledgements 4.6.5.1 for details.

6.10 Tango::Database

A high level object which contains the link to the database. It has methods for all database commands e.g. get_device_property(), device_list(), info(), etc.

6.10.1 Database::Database()

Create a TANGO Database object. The constructor uses the environment variable “TANGO_HOST” to determine which instance of the TANGO database to connect to. Example:

```
using namespace Tango;

Database *db = new Database();
```
6.10.2 string Database::get_info()

Query the database for some general info about the tables in the database. Result is returned as a string. Example:

```
cout << db->get_info() << endl;
```

will return information like this:

```
Running since 2000-11-06 14:10:46
Devices defined = 115
Devices exported = 41
Device servers defined = 47
Device servers exported = 17
Class properties defined = 5
Device properties defined = 130
Class attribute properties defined = 20
Device attribute properties defined = 92
```

Exceptions: ConnectionFailed, CommunicationFailed, DevFailed from device (DB_SQLError)

6.10.3 void Database::add_device(DbDevInfo&)

Add a device to the database. The device name, server and class are specified in the DbDevInfo structure. Example:

```
DbDevInfo my_device_info;
my_device_info.name = "my/own/device";
my_device_info.class = "MyDevice";
my_device_info.server = "MyServer/test";
db->add_device(my_device_info);
```

Exception: ConnectionFailed, CommunicationFailed, DevFailed from device

6.10.4 void Database::delete_device(string)

Delete the device of the specified name from the database. Example:

```
db->delete_device("my/own/device");
```

Exceptions: ConnectionFailed, CommunicationFailed, DevFailed from device (DB_SQLError, DB_DeviceNotDefined)
6.10.5 DbDevImportInfo Database: import _device(string &)
Query the database for the export info of the specified device. The command returns the information in a DbDevImportInfo structure. Example:

```cpp
DbDevImportInfo my_device_import;
my_device_import = db->import_device(“my/own/device”);
cout << “ device” << my_device_import.name;
cout << “exported” << my_device_import.exported;
cout << “ior” << my_device_import.ior;
cout << “version” << my_device_import.version;
cout << endl;
```

Exceptions: ConnectionFailed, CommunicationFailed, DevFailed from device (DB_SQLError, DB_DeviceNotDefined)

6.10.6 void Database: export _device(DbDevExportInfo&)
Update the export info for this device in the database. Device name, server, class, pid and version are specified in the DbDevExportInfo structure. Example:

```cpp
DbDevExportInfo my_device_export;
my_device_export.name = “my/own/device”;
my_device_export.ior = “the real ior”;
my_device_export.host = “dummy”;
my_device_export.version = “1.0”;
my_device_export.pid = get_pid();
db->export_device(my_device_export);
```

Exceptions: ConnectionFailed, CommunicationFailed, DevFailed from device (DB_SQLError, DB_DeviceNotDefined)

6.10.7 void Database::unexport _device(string)
Mark the specified device as un-exported in the database. Example:

```cpp
db->unexport_device(“my/own/device”);
```

Exceptions: ConnectionFailed, CommunicationFailed, DevFailed from device (DB_SQLError)

6.10.8 void Database::add _server(string &, DbDevInfos&)
Add a group of devices to the database. The device names, server names and classes are specified in the vector of DbDevInfo structures.

Exceptions: ConnectionFailed, CommunicationFailed, DevFailed from device (DB_SQLError)
6.10.9 void Database::delete_server(string &)
Delete the device server and its associated devices from the database.
Exceptions: ConnectionFailed, CommunicationFailed, DeviceFailed from device (DB_SQLError)

6.10.10 void Database::export_server(DbDevExportInfos &)
Export a group of devices to the database. The device names, IOR, class, server name, pid etc.
are specified in the vector of DbDevExportInfo structures.
Exceptions: ConnectionFailed, CommunicationFailed, DeviceFailed from device (DB_SQLError)

6.10.11 void Database::unexport_server(string &)
Mark all devices exported for this server as unexported.
Exceptions: ConnectionFailed, CommunicationFailed, DeviceFailed from device (DB_SQLError)

6.10.12 DbDatum Database::get_device_name(string &, string &)
Query the database for a list of devices served by the specified server (1st parameter) and of the
specified class (2nd parameter). The method returns a DbDatum type. The device names are
stored as an array of strings. Here is two code example of how to extract the names from the
DbDatum type:

```cpp
vector<string> device_names;
device_names << db_datum;
```
or:

```cpp
for (int i=0; i< db_datum.size(); i++)
{
    device_name[i] = db_datum.value_string[i];
}
```

Exception: ConnectionFailed, CommunicationFailed, DeviceFailed from device

6.10.13 DbDatum Database::get_device_exported(string &)
Query the database for a list of exported devices whose names satisfy the supplied filter (*
is wildcard for any character(s)). This method returns a DbDatum type. See the method
get_device_name() for an example of how to extract the list of aliases from the DbDatum type.
Exceptions: ConnectionFailed, CommunicationFailed, DeviceFailed from device (DB_SQLError)

6.10.14 DbDatum Database::get_device_domain(string &)
Query the database for a list of device domain names which match the wildcard provided. Wildcard
character is * and matches any number of characters. Domain names are case insensitive. This
method returns a DbDatum type. See the method get_device_name() for an example of how to
extract the list of aliases from the DbDatum type.
Exceptions: ConnectionFailed, CommunicationFailed, DeviceFailed from device (DB_SQLError)
6.10.15  DbDatum Database::get_device_family(string &)
Query the database for a list of device family names which match the wildcard provided. Wildcard
character is * and matches any number of characters. Family names are case insensitive. This
method returns a DbDatum type. See the method get_device_name() for an example of how to
extract the list of aliases from the DbDatum type.
Exceptions: ConnectionFailed, CommunicationFailed, DevFailed from device (DB_SQLError)

6.10.16  DbDatum Database::get_device_member(string &)
Query the database for a list of device member names which match the wildcard provided. Wild-

card characters is * and matches any number of characters. Member names are case insensitive.
This method returns a DbDatum type. See the method get_device_name() for an example of
how to extract the list of aliases from the DbDatum type.
Exceptions: ConnectionFailed, CommunicationFailed, DevFailed from device (DB_SQLError)

6.10.17  void Database::get_property(string, DbData&)
Query the database for a list of object (i.e. non-device) properties for the specified object. The
property names are specified by the vector of DbDatum structures. The method returns the
properties in the same DbDatum structures. To retrieve the properties use the extract operator
>>&. Here is an example of how to use the DbData type to specify and extract properties:

```c++
DbData db_data;
    db_data.push_back(DbDatum("velocity"));
    db_data.push_back(DbDatum("acceleration"));
    db->get_property("mymotor", db_data);
    float velocity, acceleration;
    db_data[0] >> velocity;
    db_data[1] >> acceleration;
```

Exceptions: ConnectionFailed, CommunicationFailed, DevFailed from device (DB_SQLError)

6.10.18  void Database::put_property(string, DbData&)
Insert or update a list of properties for the specified object. The property names and their values
are specified by the vector of DbDatum structures. Use the insert operator >> to insert the
properties into the DbDatum structures. Here is an example of how to insert properties into the
database using this method:

```c++
DbDatum velocity("velocity"), acceleration("acceleration");
DbData db_data;
    velocity <<= 100000.0;
    acceleration <<= 500000.0;
    db_data.push_back(velocity);
    db_data.push_back(acceleration);
    db->put_property("mymotor", db_data);
```

Exceptions: ConnectionFailed, CommunicationFailed, DevFailed from device (DB_SQLError)
6.10.19 void Database::delete_property(string, DbData&)
Delete a list of properties for the specified object. The property names are specified by the vector of DbDatum structures. Here is an example of how to delete properties from the database using this method:

```cpp
DbData db_data;
db_data.push_back(DbDatum("velocity"));
db_data.push_back(DbDatum("acceleration"));
db->delete_property("mymotor", db_data);
```

*Exceptions: ConnectionFailed, CommunicationFailed, DevFailed from device*

6.10.20 void Database::get_device_property(string, DbData&)
Query the database for a list of device properties for the specified object. The property names are specified by the vector of DbDatum structures. The method returns the properties in the same DbDatum structures. To retrieve the properties use the extract operator >>. Here is an example of how to use the DbData type to specify and extract properties:

```cpp
DbData db_data;
db_data.push_back(DbDatum("velocity"));
db_data.push_back(DbDatum("acceleration"));
db->get_device_property("id11/motor/1", db_data);
float velocity, acceleration;
db_data[0] >> velocity;
db_data[1] >> acceleration;
```

*Exceptions: ConnectionFailed, CommunicationFailed, DevFailed from device (DB_SQLERROR)*

6.10.21 void Database::put_device_property(string, DbData&)
Insert or update a list of properties for the specified device. The property names and their values are specified by the vector of DbDatum structures. Use the insert operator >> to insert the properties into the DbDatum structures. Here is an example of how to insert properties into the database using this method:

```cpp
DbDatum velocity("velocity"), acceleration("acceleration");
DbData db_data;
velocity << 100000.0;
acceleration << 500000.0;
db_data.push_back(velocity);
db_data.push_back(acceleration);
db->put_device_property("id11/motor/1", db_data);
```

*Exceptions: ConnectionFailed, CommunicationFailed, DevFailed from device (DB_SQLERROR)*
6.10.22 void Database::delete_device_property(string, DbData&)

Delete a list of properties for the specified device. The property names are specified by the vector of DbDatum structures. Here is an example of how to delete properties from the database using this method:

```
DbData db_data;
db_data.push_back(DbDatum("velocity"));
db_data.push_back(DbDatum("acceleration"));
db->delete_device_property("id1/motor/1", db_data);
```

Exceptions: ConnectionFailed, CommunicationFailed, DevFailed from device (DB_SQLError)

6.10.23 void Database::get_device_attribute_property(string, DbData&)

Query the database for a list of device attribute properties for the specified object. The attribute names are specified by the vector of DbDatum structures. The method returns all the properties for the specified attributes. The attribute names are returned with the number of properties specified as their value. The first DbDatum element of the returned DbData vector contains the first attribute name and the first attribute property number. The following DbDatum element contains the first attribute property name and property values. To retrieve the properties use the extract operator >>. Here is an example of how to use the DbData type to specify and extract attribute properties:

```
DbData db_data;
db_data.push_back(DbDatum("velocity"));
db_data.push_back(DbDatum("acceleration"));

db->get_device_attribute_property("id1/motor/1", db_data);

float vel_max, vel_min, acc_max, acc_min;

for (int i=0; i< db_data.size(); i++)
{
    long nb_prop;
    string &att_name = db_data[i].name;
    db_data[i] >> nb_prop;
    
    for (int k=0; k < nb_prop; k++)
    {
        string &prop_name = db_data[i].name;
        if (att_name == "velocity")
        {
            if (prop_name == "min")
                db_data[i] >> vel_min;
            else if (att_name == "max")
                db_data[i] >> vel_max;
        }
        else
        {
```
```cpp
if (prop_name == "min")
    db_data[i] >> acc_min;
else
    db_data[i] >> acc_max;
}
i++;
}
```

**Exceptions:** ConnectionFailed, CommunicationFailed, DevFailed from device (DB_SQLError)

### 6.10.24 void Database::put_device_attribute_property(const string, DbData&)

Insert or update a list of attribute properties for the specified device. The attribute property names and their values are specified by the vector of DbDatum structures. Use the insert operator `>>` to insert the properties into the DbDatum structures. Here is an example of how to insert/update properties `min`, `max` for attribute `velocity` and properties `min`, `max` for attribute `acceleration` of device `id11/motor/1` into the database using this method:

```cpp
DbDatum velocity("velocity"), vel_min("min"), vel_max("max");
DbDatum acceleration("acceleration"), acc_min("min"), acc_max("max");
DbData db_data;
velocity <<= 2;
vel_min <<= 0.0;
vel_max <<= 1000000.0;
db_data.push_back(velocity);
db_data.push_back(vel_min);
db_data.push_back(vel_max);
acceleration <<= 2;
acc_min <<= 0.0;
acc_max <<= 8000000;
db_data.push_back(acceleration);
db_data.push_back(acc_min);
db_data.push_back(acc_max);
db->put_device_attribute_property("id11/motor/1", db_data);
```

**Exceptions:** ConnectionFailed, CommunicationFailed, DevFailed from device (DB_SQLError)

### 6.10.25 void Database::delete_device_attribute_property(const string, DbData&)

Delete a list of attribute properties for the specified device. The attribute names are specified by the vector of DbDatum structures. Here is an example of how to delete the `unit` property of the `velocity` attribute of the `id11/motor/1` device using this method:

```cpp
DbData db_data;
db_data.push_back(DbDatum("velocity"));
db_data.push_back(DbDatum("unit"));
db->delete_device_attribute_property("id11/motor/1", db_data);
```
Exceptions: ConnectionFailed, CommunicationFailed, DevFailed from device (DB_SQLException)

6.10.26 void Database::get_class_property(string, DbData&)
Query the database for a list of class properties. The property names are specified by the vector of DbDatum structures. The method returns the properties in the same DbDatum structures. To retrieve the properties use the extract operator >> . Here is an example of how to use the DbData type to specify and extract properties:

```cpp
DbData db_data;
db_data.push_back(DbDatum("velocity"));
db_data.push_back(DbDatum("acceleration"));
db->get_class_property("StepperMotor", db_data);
float velocity, acceleration;
db_data[0] >> velocity;
db_data[1] >> acceleration;
```

Exceptions: ConnectionFailed, CommunicationFailed, DevFailed from device (DB_SQLException)

6.10.27 void Database::put_class_property(string, DbData&)
Insert or update a list of properties for the specified class. The property names and their values are specified by the vector of DbDatum structures. Use the insert operator >> to insert the properties into the DbDatum structures. Here is an example of how to insert properties into the database using this method:

```cpp
DbDatum velocity("velocity"), acceleration("acceleration");
DbData db_data;
velocity << 100000.0;
acceleration << 500000.0;
db_data.push_back(velocity);
db_data.push_back(acceleration);
db->put_class_property("StepperMotor", db_data);
```

Exceptions: ConnectionFailed, CommunicationFailed, DevFailed from device (DB_SQLException)

6.10.28 void Database::delete_class_property(string, DbData&)
Delete a list of properties for the specified class. The property names are specified by the vector of DbDatum structures. Here is an example of how to delete properties from the database using this method:

```cpp
DbData db_data;
db_data.push_back(DbDatum("velocity"));
db_data.push_back(DbDatum("acceleration"));
db->delete_class_property("StepperMotor", db_data);
```

Exceptions: ConnectionFailed, CommunicationFailed, DevFailed from device (DB_SQLException)
6.10.29 void Database::get_class_attribute_property(string, DbData&)

Query the database for a list of class attribute properties for the specified object. The attribute names are specified by the vector of DbDatum structures. The method returns all the properties for the specified attributes. The attribute names are returned with the number of properties specified as their value. The first DbDatum element of the returned DbData vector contains the first attribute name and the first attribute property number. The following DbDatum element contains the first attribute property name and property values. To retrieve the properties use the extract operator >>. Here is an example of how to use the DbData type to specify and extract attribute properties:

```c++
DbData db_data;
  db_data.push_back(DbDatum("velocity"));
  db_data.push_back(DbDatum("acceleration"));

  db->get_class_attribute_property("StepperMotor", db_data);

  float vel_max, vel_min, acc_max, acc_min;

  for (int i=0; i< db_data.size(); i++)
  {
    long nb_prop;
    string &att_name = db_data[i].name;
    db_data[i] >> nb_prop;
    i++;
    for (int k=0; k < nb_prop; k++)
    {
      string &prop_name = db_data[i].name;
      if (att_name == "velocity")
      {
        if (prop_name == "min")
          db_data[i] >> vel_min;
        else if (att_name == "max")
          db_data[i] >> vel_max;
      }
      else
      {
        if (prop_name == "min")
          db_data[i] >> acc_min;
        else
          db_data[i] >> acc_max;
      }
    }
  }
```

Exceptions: ConnectionFailed, CommunicationFailed, DevFailed from device (DB_SQLException)

6.10.30 void Database::put_class_attribute_property(string, DbData&)

Insert or update a list of attribute properties for the specified class. The attribute property names and their values are specified by the vector of DbDatum structures. Use the insert operator >>
to insert the properties into the DbDatum structures. Here is an example of how to insert/update min, max properties for attribute velocity and min, max properties for attribute acceleration properties belonging to class StepperMotor into the database using this method:

```cpp
DbDatum velocity("velocity"), vel_min("min"), vel_max("max");
DbDatum acceleration("acceleration"), acc_min("min"), acc_max("max");
DbData db_data;
velocity <<= 2;
vel_min <<= 0.0;
vel_max <<= 1000000.0;
db_data.push_back(velocity);
db_data.push_back(vel_min);
db_data.push_back(vel_max);
acceleration <<= 2;
acc_min <<= 0.0;
acc_max <<= 8000000;
db_data.push_back(acceleration);
db_data.push_back(acc_min);
db_data.push_back(acc_max);
db->put_class_attribute_property("StepperMotor", db_data);
```

Exceptions: ConnectionFailed, CommunicationFailed, DevFailed from device (DB_SQLError)

### 6.10.31 void Database::delete_class_attribute_property(string, DbData&)

Delete a list of attribute properties for the specified class. The attribute names are specified by the vector of DbDatum structures. All properties belonging to the listed attributes are deleted. Here is an example of how to delete the unit property of the velocity attribute of the StepperMotor class from the database using this method:

```cpp
DbData db_data;
db_data.push_back(DbDatum("velocity"));
db_data.push_back(DbDatum("unit"));
db->delete_class_attribute_property("StepperMotor", db_data);
```

Exceptions: ConnectionFailed, CommunicationFailed, DevFailed from device (DB_SQLError)

### 6.10.32 void Database::get_alias(string dev_name, string &dev_alias)

Get the device alias name from its name. The device name is specified by dev_name and the device alias name is returned in dev_alias. If there is no alias defined for the device, a DevFailed exception is thrown.

Exceptions: ConnectionFailed, CommunicationFailed, DevFailed from device (DB_AliasNotDefined)

### 6.10.33 void Database::get_device_alias(string dev_alias, string &dev_name)

Get the device name from an alias. The device alias is specified by dev_alias and the device name is returned in dev_name. If there is no device with the given alias, a DevFailed exception is thrown.

Exceptions: ConnectionFailed, CommunicationFailed, DevFailed from device (DB_DeviceNotDefined)
6.10.34  void Database::get_attribute_alias(string attr_alias, string &attr_name)

Get the full attribute name from an alias. The attribute alias is specified by attr_alias and the full attribute name is returned in attr_name. If there is no attribute with the given alias, a DevFailed exception is thrown.

Exceptions: ConnectionFailed, CommunicationFailed, DevFailed from device (DB_SQLError)

6.10.35  DbDatum Database::get_device_alias_list(string &filter)

Get device alias list. The parameter alias is a string to filter the alias list returned. Wildcard (*) is supported. For instance, if the string alias passed as the method parameter is initialised with only the * character, all the defined device alias will be returned. The DbDatum returned by this method is initialised with an array of strings and must be extracted into a vector<string>. If there is no alias with the given filter, the returned array will have a 0 size.

```cpp
DbData db_data;
string filter("*");
  db_data = db->get_device_alias_list(filter);
  vector<string> al_list;
  db_data >> al_list;
  cout << al_list.size() << " device alias defined in db" << endl;
  for (int i=0;i < al_list.size();i++)
    cout << "alias = " << al_list[i] << endl;
```

Exceptions: ConnectionFailed, CommunicationFailed, DevFailed from device (DB_SQLError)

6.10.36  DbDatum Database::get_attribute_alias_list(string &filter)

Get attribute alias list. The parameter alias is a string to filter the alias list returned. Wildcard (*) is supported. For instance, if the string alias passed as the method parameter is initialised with only the * character, all the defined attribute alias will be returned. The DbDatum returned by this method is initialised with an array of strings and must be extracted into a vector<string>. If there is no alias with the given filter, the returned array will have a 0 size.

Exceptions: ConnectionFailed, CommunicationFailed, DevFailed from device (DB_SQLError)

6.11  Tango::DbDevice

A database object for a device which can be used to query or modify properties, import and export information for a device. This class provides an easy to use interface for device objects in the database. It uses the methods of the Database class therefore the reader is referred to these for the exact calling syntax and examples. The following methods are defined for the DbDevice class :

6.11.1  DbDevice::DbDevice(string &)

A constructor for a DbDevice object for a device in the TANGO database specified by the TANGO_HOST environment variable.

6.11.2  DbDevice::DbDevice(string &, Database *)

A constructor for a DbDevice object for the device in the specified database. This method reuses the Database supplied by the programmer.
6.11.3 DbDevImportInfo DbDevice::import_device()
Query the database for the import info of this device. Returns a DbDevImportInfo structure.
Exceptions: ConnectionFailed, CommunicationFailed, DevFailed from device (DB_SQLError)

6.11.4 void DbDevice::export_device(DbDevExportInfo&)
Update the export info for this device in the database.
Exceptions: ConnectionFailed, CommunicationFailed, DevFailed from device (DB_SQLError)

6.11.5 void DbDevice::add_device(DbDevInfo&)
Add/Update this device to the database.
Exceptions: ConnectionFailed, CommunicationFailed, DevFailed from device (DB_SQLError)

6.11.6 void DbDevice::delete_device()
Delete this device from the database.
Exceptions: ConnectionFailed, CommunicationFailed, DevFailed from device (DB_SQLError)

6.11.7 void DbDevice::get_property(DbData&)
Query the database for the list of properties of this device. See Database::get_device_property() for an example of how to specify and retrieve the properties.
Exceptions: ConnectionFailed, CommunicationFailed, DevFailed from device (DB_SQLError)

6.11.8 void DbDevice::put_property(DbData&)
Update the list of properties for this device in the database. See Database::put_device_property() for an example of how to specify the properties.
Exceptions: ConnectionFailed, CommunicationFailed, DevFailed from device (DB_SQLError)

6.11.9 void DbDevice::delete_property(DbData&)
Delete the list of specified properties for this device in the database. See Database::delete_property() for an example of how to specify the properties.
Exceptions: ConnectionFailed, CommunicationFailed, DevFailed from device (DB_SQLError)

6.11.10 void DbDevice::get_attribute_property(DbData&)
Query the database for the list of attribute properties of this device. See Database::get_device_attribute_property() for an example of how to specify and retrieve the properties.
Exceptions: ConnectionFailed, CommunicationFailed, DevFailed from device (DB_SQLError)

6.11.11 void DbDevice::put_attribute_property(DbData&)
Update the list of attribute properties for this device in the database. See Database::put_device_attribute_property() for an example of how to specify the properties.
Exceptions: ConnectionFailed, CommunicationFailed, DevFailed from device (DB_SQLError)

6.11.12 void DbDevice::delete_attribute_property(DbData&)
Delete all properties for the list of specified attributes for this device in the database. See Database::delete_device_attribute_property() for an example of how to specify the properties.
Exceptions: ConnectionFailed, CommunicationFailed, DevFailed from device (DB_SQLError)
6.12 Tango::DbClass

A database object for a class which can be used to query or modify class properties.

6.12.1 DbClass::DbClass(string)

A constructor for a DbClass object for a class in the TANGO database specified by the TANGO_HOST environment variable.

6.12.2 DbClass::DbClass(string, Database *)

A constructor for a DbClass object for the class in the specified database. This method reuses the Database supplied by the programmer.

6.12.3 void DbClass::get_property(DbData&)

Query the database for the list of properties of this class. See Database::get_class_property() for an example of how to specify and retrieve the properties.

Exceptions: ConnectionFailed, CommunicationFailed, DevFailed from device (DB_SQLError)

6.12.4 void DbClass::put_property(DbData&)

Update the list of properties for this class in the database. See Database::put_class_property() for an example of how to specify the properties.

Exceptions: ConnectionFailed, CommunicationFailed, DevFailed from device (DB_SQLError)

6.12.5 void DbClass::delete_property(DbData&)

Delete the list of specified properties for this class in the database. See Database::delete_property() for an example of how to specify the properties.

Exceptions: ConnectionFailed, CommunicationFailed, DevFailed from device (DB_SQLError)

6.12.6 void DbClass::get_attribute_property(DbData&)

Query the database for the list of attribute properties of this class. See Database::get_class_attribute_property() for an example of how to specify and retrieve the properties.

Exceptions: ConnectionFailed, CommunicationFailed, DevFailed from device (DB_SQLError)

6.12.7 void DbClass::put_attribute_property(DbData&)

Update the list of attribute properties for this class in the database. See Database::put_class_attribute_property() for an example of how to specify the properties.

Exceptions: ConnectionFailed, CommunicationFailed, DevFailed from device (DB_SQLError)

6.12.8 void DbClass::delete_attribute_property(DbData&)

Delete all properties for the list of specified attributes for this class in the database. See Database::delete_class_attribute() for an example of how to specify the properties.

Exceptions: ConnectionFailed, CommunicationFailed, DevFailed from device (DB_SQLError)

6.13 Tango::DbServer

A database object for a device server which can be used to query or modify server database information.
6.13.1 `DbServer::DbServer(string)`

A constructor for a `DbServer` object for a server in the TANGO database specified by the TANGO_HOST environment variable.

6.13.2 `DbServer::DbServer(string, Database *)`

A constructor for a `DbServer` object for the server in the specified database. This method reuses the database supplied by the programmer.

6.13.3 `void DbServer::add_server(DbDevInfos &)`

Add a group of devices to the database. The device names, server names and classes are specified in the vector of DbDevInfo structures.

*Exceptions: ConnectionFailed, CommunicationFailed, DevFailed from device (DB_SQLError)*

6.13.4 `void DbServer::delete_server()`

Delete the device server and its associated devices from the database.

*Exceptions: ConnectionFailed, CommunicationFailed, DevFailed from device (DB_SQLError)*

6.13.5 `void DbServer::export_server(DbDevExportInfos &)`

Export a group of device to the database. The device names, IOR, class, server name, pid etc. are specified in the vector of DbDevExportInfo structures.

*Exceptions: ConnectionFailed, CommunicationFailed, DevFailed from device (DB_SQLError)*

6.13.6 `void DbServer::unexport_server()`

Mark all the devices exported by the server as un exported.

*Exceptions: ConnectionFailed, CommunicationFailed, DevFailed from device (DB_SQLError)*

6.14 `Tango::DbDatum`

A single database value which has a name, type, address and value and methods for inserting and extracting C++ native types. This is the fundamental type for specifying database properties. Every property has a name and has one or more values associated with it. The values can be inserted and extracted using the operators `<` and `>` respectively. A status flag indicates if there is data in the `DbDatum` object or not. An additional flag allows the user to activate exceptions.

6.14.1 `Operators`

The insert and extract operators are specified for the following C++ types:

1. boolean
2. unsigned char
3. short
4. unsigned short
5. long
6. unsigned long
7. float
8. double
9. string
10. char* (insert only)
11. const char *
12. vector<string>
13. vector<short>
14. vector<unsigned short>
15. vector<long>
16. vector<unsigned long>
17. vector<float>
18. vector<double>

Here is an example of creating, inserting and extracting some DbDatum types:

```cpp
DbDatum my_short("my_short"), my_long("my_long"), my_string("my_string");
DbDatum my_float_vector("my_float_vector"), my_double_vector("my_double_vector");
string a_string;
short a_short;
long a_long;
vector<float> a_float_vector;
vector<double> a_double_vector;
my_short << 100; // insert a short
my_short >> a_short; // extract a short
my_long << 1000; // insert a long
my_long >> a_long; // extract a long
my_string << string("Estás lista a bailar el tango?"); // insert a string
my_string >> a_string; // extract a string
my_float_vector << a_float_vector; // insert a vector of floats
my_float_vector >> a_float_vector; // extract a vector of floats
my_double_vector << a_double_vector; // insert a vector of doubles
my_double_vector >> a_double_vector; // extract a vector of doubles
```

Exception: WrongData if requested

6.14.2 bool DbDatum::is_empty()

is_empty() is a boolean method which returns true or false depending on whether the DbDatum object contains data or not. It can be used to test whether a property is defined in the database or not e.g.
sl_props.push_back(parity_prop);
dbase->get_device_property(device_name, sl_props);
if (! parity_prop.is_empty())
{
    parity_prop >> parity;
}
else
{
    cout << device_name << " has no parity defined in database!" << endl;
}

**Exception: WrongData if requested**

**6.14.3 void DbDatum::exceptions(bitset<DbDatum::numFlags>)**

Is a method which allows the user to switch on/off exception throwing for trying to extract data from an empty DbDatum object. The default is to not throw exception. The following flags are supported:

1. **isempty_flag** - throw a WrongData exception (reason = API_EmptyDbDatum) if user tries to extract data from an empty DbDatum object

2. **wrongtype_flag** - throw a WrongData exception (reason = API_IncompatibleArgumentType) if user tries to extract data with a type different than the type used for insertion

**6.14.4 bitset<DbDatum::numFlags> exceptions()**

Returns the whole exception flags.

**6.14.5 void DbDatum::reset_exceptions(DbDatum::except_flags fl)**

Resets one exception flag

**6.14.6 void DbDatum::set_exceptions(DbDatum::except_flags fl)**

Sets one exception flag

The following is an example of how to use these exceptions related methods:

```
1  DbDatum da;
2  bitset<DbDatum::numFlags> bs = da.exceptions();
3  cout << "bs = " << bs << endl;
4  da.set_exceptions(DbDatum::wrongtype_flag);
5  bs = da.exceptions();
6  cout << "bs = " << bs << endl;
```
6.15 Tango::DbData

A vector of Tango::DbDatum structures. DbData is used to send or return one or more database properties or information. It is the standard input and output type for all methods which query and/or update properties in the database.

6.16 Exception

All the exception thrown by this API are Tango::DevFailed exception. This exception is a variable length array of Tango::DevError type. The Tango::DevError type is a four fields structure. These fields are:

1. A string describing the error type. This string replaces an error code and allows a more easy management of include files. This field is called reason
2. A string describing in plain text the reason of the error. This field is called desc
3. A string giving the name of the method which thrown the exception. This field is named origin
4. The error severity. This is an enumeration with three values which are WARN, ERR or PANIC. Its name is severity

This is a variable length array in order to transmit to the client what is the primary error reason. The sequence element 0 describes the primary error. An exception class hierarchy has been implemented within the API to ease API programmers task. All the exception classes inherits from the Tango::DevFailed class. Except for the NamedDevFailedList exception class, they don’t add any new fields to the exception, they just allow easy "catching". Exception classes thrown only by the API layer are:

- ConnectionFailed
- CommunicationFailed
- WrongNameSyntax
- NonDbDevice
- WrongData
- NonSupportedFeature
- AsynCall
- AsynReplyNotArrived
- EventSystemFailed
- NamedDevFailedList

On top of these classes, exception thrown by the device (Tango::DevFailed exception) are directly passed to the client.

6.16.1 The ConnectionFailed exception

This exception is thrown when a problem occurs during the connection establishment between the application and the device. The API is stateless. This means that DeviceProxy constructors filter most of the exception except for cases described in the following table.
<table>
<thead>
<tr>
<th>Method name</th>
<th>device type</th>
<th>error type</th>
<th>Level</th>
<th>reason</th>
</tr>
</thead>
<tbody>
<tr>
<td>DeviceProxy</td>
<td>with database</td>
<td>TANGO_HOST not set</td>
<td>0</td>
<td>API_TangoHostNotSet</td>
</tr>
<tr>
<td>constructor</td>
<td></td>
<td>Device not defined in db</td>
<td>1</td>
<td>API_DeviceNotDefined</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Alias not defined in db</td>
<td>2</td>
<td>API_DeviceNotDefined</td>
</tr>
<tr>
<td></td>
<td>with database</td>
<td>Database server not running</td>
<td>1</td>
<td>API_CorbaException</td>
</tr>
<tr>
<td></td>
<td>specified in dev name</td>
<td></td>
<td>0</td>
<td>API_CorbaException</td>
</tr>
<tr>
<td></td>
<td>without database</td>
<td>Server running but device not defined in server</td>
<td>1</td>
<td>API_DeviceNotExported</td>
</tr>
<tr>
<td>AttributeProxy</td>
<td>with database</td>
<td>TANGO_HOST not set</td>
<td>0</td>
<td>API_TangoHostNotSet</td>
</tr>
<tr>
<td>constructor</td>
<td></td>
<td>Device not defined in db</td>
<td>1</td>
<td>API_DeviceNotDefined</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Alias not defined in db</td>
<td>2</td>
<td>API_DeviceNotDefined</td>
</tr>
<tr>
<td></td>
<td>with database</td>
<td>Database server not running</td>
<td>0</td>
<td>API_CorbaException</td>
</tr>
<tr>
<td></td>
<td>specified in dev name</td>
<td></td>
<td>1</td>
<td>API_CorbaException</td>
</tr>
<tr>
<td></td>
<td>without database</td>
<td>Server not running</td>

<td>API_CorbaException</td>
</tr>
<tr>
<td>DeviceProxy</td>
<td>with database</td>
<td>Server not running</td>
<td>1</td>
<td>API_CorbaException</td>
</tr>
<tr>
<td>method call</td>
<td></td>
<td>Dead server</td>
<td>1</td>
<td>API_DeviceNotExported</td>
</tr>
<tr>
<td>(except cmd_inout</td>
<td></td>
<td>Dead database server</td>
<td>0</td>
<td>API_CorbaException</td>
</tr>
<tr>
<td>read_attribute)</td>
<td></td>
<td>when reconnection needed</td>
<td>1</td>
<td>API_CorbaException</td>
</tr>
<tr>
<td>DeviceProxy</td>
<td>without database</td>
<td>Server not running</td>
<td>1</td>
<td>API_DeviceNotDefined</td>
</tr>
<tr>
<td>cmd_inout and</td>
<td></td>
<td>Dead server</td>
<td>1</td>
<td>API_DeviceNotExported</td>
</tr>
<tr>
<td>read_attribute</td>
<td></td>
<td>Dead database server</td>
<td>0</td>
<td>API_CorbaException</td>
</tr>
<tr>
<td>or AttributeProxy</td>
<td></td>
<td></td>
<td>1</td>
<td>API_CorbaException</td>
</tr>
<tr>
<td>read and write</td>
<td></td>
<td></td>
<td>1</td>
<td>API_CorbaException</td>
</tr>
</tbody>
</table>

The desc DevError structure field allows a user to get more precise information. These informations are:

**DB_DeviceNotDefined** The name of the device not defined in the database

**API_CommandFailed** The device and command name

**API_CantConnectToDevice** The device name

**API_CorbaException** The name of the CORBA exception, its reason, its locality, its completed flag and its minor code

**API_CantConnectToDatabase** The database server host and its port number

**API_DeviceNotExported** The device name
6.16.2 The CommunicationFailed exception

This exception is thrown when a communication problem is detected during the communication between the client application and the device server. It is a two level Tango::DevError structure. In case of time-out, the DevError structures fields are:

<table>
<thead>
<tr>
<th>Level</th>
<th>Reason</th>
<th>Desc</th>
<th>Severity</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>API_CorbaException</td>
<td>CORBA exception fields translated into a string</td>
<td>ERR</td>
</tr>
<tr>
<td>1</td>
<td>API_DeviceTimedOut</td>
<td>String with time-out value and device name</td>
<td>ERR</td>
</tr>
</tbody>
</table>

For all other communication errors, the DevError structures fields are:

<table>
<thead>
<tr>
<th>Level</th>
<th>Reason</th>
<th>Desc</th>
<th>Severity</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>API_CorbaException</td>
<td>CORBA exception fields translated into a string</td>
<td>ERR</td>
</tr>
<tr>
<td>1</td>
<td>API_CommunicationFailed</td>
<td>String with device, method, command/attribute name</td>
<td>ERR</td>
</tr>
</tbody>
</table>

6.16.3 The WrongNameSyntax exception

This exception has only one level of Tango::DevError structure. The possible value for the reason field are:

API_UnsupportedProtocol This error occurs when trying to build a DeviceProxy or an AttributeProxy instance for a device with an unsupported protocol. Refer to the appendix on device naming syntax to get the list of supported database modifier

API_UnsupportedDBaseModifier This error occurs when trying to build a DeviceProxy or an AttributeProxy instance for a device/attribute with a database modifier unsupported. Refer to the appendix on device naming syntax to get the list of supported database modifier

API_WrongDeviceNameSyntax This error occurs for all the other error in device name syntax. It is thrown by the DeviceProxy class constructor.

API_WrongAttributeNameSyntax This error occurs for all the other error in attribute name syntax. It is thrown by the AttributeProxy class constructor.

6.16.4 The NonDbDevice exception

This exception has only one level of Tango::DevError structure. The reason field is set to API_NonDatabaseDevice. This exception is thrown by the API when using the DeviceProxy or AttributeProxy class database access for non-database device.
CHAPTER 6. THE TANGO C++ APPLICATION PROGRAMMER INTERFACE

6.16.5 The WrongData exception
This exception has only one level of Tango::DevError structure. The possible value for the reason field are:

API_EmptyDbDatum This error occurs when trying to extract data from an empty DbDatum object.
API_IncompatibleArgumentType This error occurs when trying to extract data with a type different than the type used to send the data.
API_EmptyDeviceAttribute This error occurs when trying to extract data from an empty DeviceAttribute object.
API_IncompatibleAttrArgumentType This error occurs when trying to extract attribute data with a type different than the type used to send the data.
API_EmptyDeviceData This error occurs when trying to extract data from an empty DeviceData object.
API_IncompatibleCmdArgumentType This error occurs when trying to extract command data with a type different than the type used to send the data.

6.16.6 The NonSupportedFeature exception
This exception is thrown by the API layer when a request to a feature implemented in Tango device interface release n is requested for a device implementing Tango device interface n-x. There is one possible value for the reason field which is API_UnsupportedFeature.

6.16.7 The AsynCall exception
This exception is thrown by the API layer when a the asynchronous model id badly used. This exception has only one level of Tango::DevError structure. The possible value for the reason field are:

API_BadAsynPollId This error occurs when using an asynchronous request identifier which is not valid anymore.
API_BadAsyn This error occurs when trying to fire callback when no callback has been previously registered.
API_BadAsynReqType This error occurs when trying to get result of an asynchronous request with an asynchronous request identifier returned by a non-coherent asynchronous request (For instance, using the asynchronous request identifier returned by a command_inout_asynch() method with a read_attribute_reply() attribute).

6.16.8 The AsynReplyNotArrived exception
This exception is thrown by the API layer when:

- a request to get asynchronous reply is made and the reply is not yet arrived
- a blocking wait with timeout for asynchronous reply is made and the timeout expired.

There is one possible value for the reason field which is API_AsynReplyNotArrived.
6.16.9 The EventSystemFailed exception

This exception is thrown by the API layer when subscribing or unsubscribing from an event failed. This exception has only one level of Tango::DevError structure. The possible value for the reason field are:

API_NotificationServiceFailed This error occurs when the subscribe_event() method failed trying to access the CORBA notification service.

API_EventNotFound This error occurs when you are using an incorrect event_id in the unsubscribe_event() method.

API_InvalidArgs This error occurs when NULL pointers are passed to the subscribe or unsubscribe event methods.

API_MethodArgument This error occurs when trying to subscribe to an event which has already been subscribed to.

API_DSFailedRegisteringEvent This error means that the device server to which the device belongs to failed when it tries to register the event. Most likely, it means that there is no event property defined.

API_EventNotFound Occurs when using a wrong event identifier in the unsubscribe_event method.

6.16.10 The NamedDevFailedList exception

This exception is only thrown by the DeviceProxy::write_attributes() method. In this case, it is necessary to have a new class of exception to transfer the error stack for several attribute(s) which failed during the writing. Therefore, this exception class contains for each attributes which failed:

- The name of the attribute
- Its index in the vector passed as argument of the write_attributes() method
- The error stack as described in 6.16

6.16.10.1 long NamedDevFailedList::get_faulty_attr_nb()

Returns the number of attributes which failed during the write_attribute call.

6.16.10.2 vector&lt;NamedDevFailed&gt; NamedDevErrorList::err_list

Public data member of the NamedDevFailedList. There is one element in this vector for each attribute which failed during its writing.

6.16.10.3 string NamedDevFailed::name

Public data member of the NamedDevFailed class. It contains the name of the attribute which failed.

6.16.10.4 long NamedDevFailed::idx_in_call

Public data member of the NamedDevFailed class. It contains the index in the write_attributes method parameter vector of the attribute which failed.
6.10.5 DevErrorList NamedDevFailed::err_stack
Public data member of the NamedDevFailed class. This is the error stack.
The following piece of code is an example of how to use this class exception

```c++
catch (Tango::NamedDevFailed &e)
{
    long nb_faully = e.get_faulty_attr_nb();
    for (long i = 0; i < nb_faully; i++)
    {
        cout << "Attribute " << e.err_list[i].name << " failed!" << endl;
        for (long j = 0; j < e.err_list[i].err_stack.length(); j++)
        {
            cout << "Reason [" << j << "] = " << e.err_list[i].err_stack[j].reason;
            cout << "Desc [" << j << "] = " << e.err_list[i].err_stack[j].desc;
        }
    }
}
```

This exception inherits from Tango::DevFailed. It is possible to catch it with a "catch DevFailed" catch block. In this case, like any other DevFailed exception, there is only one error stack. This stack is initialised with the name of all the attributes which failed in its "reason" field.

6.17 Reconnection and exception

The Tango API automatically manages re-connection between client and server in case of communication error during a network access between a client and a server. The transparency reconnection mode allows a user to be (or not be) informed that automatic reconnection took place. If the transparency reconnection mode is not set, when a communication error occurs, an exception is returned to the caller and the connection is internally marked as bad. On the next try to contact the device, the API will try to re-build the network connection. If the transparency reconnection mode is set, the API will try to re-build the network connection has soon as the communication error occurs and the caller is not informed. Several cases are possible. They are summarized in the following table:

<table>
<thead>
<tr>
<th>Case</th>
<th>Server state</th>
<th>call nb</th>
<th>exception (transparency false)</th>
<th>exception (transparency true)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Server killed and re-started</td>
<td>Server killed before call n</td>
<td>n</td>
<td>CommunicationFailed</td>
<td>ConnectionFailed</td>
</tr>
<tr>
<td></td>
<td>down</td>
<td>n+1</td>
<td>ConnectionFailed(2 levels)</td>
<td>idem</td>
</tr>
<tr>
<td></td>
<td>down</td>
<td>n+2</td>
<td>idem</td>
<td>idem</td>
</tr>
<tr>
<td></td>
<td>Running</td>
<td>n + x</td>
<td>No exception</td>
<td>No exception</td>
</tr>
<tr>
<td>Server died and re-started</td>
<td>Server died before call n</td>
<td>n</td>
<td>CommunicationFailed</td>
<td>ConnectionFailed</td>
</tr>
<tr>
<td></td>
<td>died</td>
<td>n+1</td>
<td>ConnectionFailed (3 levels)</td>
<td>idem</td>
</tr>
<tr>
<td></td>
<td>died</td>
<td>n+2</td>
<td>idem</td>
<td>idem</td>
</tr>
<tr>
<td></td>
<td>Running</td>
<td>n + x</td>
<td>No exception</td>
<td>No exception</td>
</tr>
<tr>
<td>Server killed and re-started</td>
<td>Server killed and re-started before call n</td>
<td>n</td>
<td>CommunicationFailed</td>
<td>No exception</td>
</tr>
<tr>
<td>-----------------------------</td>
<td>-------------------------------------------</td>
<td>---</td>
<td>---------------------</td>
<td>--------------</td>
</tr>
<tr>
<td>Running</td>
<td>n+x</td>
<td>No exception</td>
<td>No exception</td>
<td></td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Server died and re-started</th>
<th>Server died and re-started before call n</th>
<th>n</th>
<th>CommunicationFailed</th>
<th>No exception</th>
</tr>
</thead>
<tbody>
<tr>
<td>Running</td>
<td>n + x</td>
<td>No exception</td>
<td>No exception</td>
<td></td>
</tr>
</tbody>
</table>

Please note that the timeout case is managed differently because it will not enter the re-connection system.
Chapter 7

TangoATK Programmer’s Guide

This chapter is only the Tango ATK (Application ToolKit) programmers guide. You can find a reference guide with a full description of TangoATK classes and methods in [17]

7.1 Introduction

This document describes how to develop applications using the Tango Application Toolkit, TangoATK for short. It will start with a brief description of the main concepts behind the toolkit, and then continue with more practical, real-life examples to explain key parts.

7.1.1 Assumptions

The author assumes that the reader has a good knowledge of the Java programming language, and a thorough understanding of object-oriented programming. Also, it is expected that the reader is fluent in all aspects regarding Tango devices, attributes, and commands.

7.2 The key concepts of TangoATK

TangoATK was developed with these goals in mind

- TangoATK should help minimize development time
- TangoATK should help minimize bugs in applications
- TangoATK should support applications that contain attributes and commands from several different devices.
- TangoATK should help avoid code duplication.

Since most Tango-applications were foreseen to be displayed on some sort of graphic terminal, TangoATK needed to provide support for some sort of graphic building blocks. To enable this, and since the toolkit was to be written in Java, we looked to Swing to figure out how to do this.

Swing is developed using a variant over a design-pattern the Model-View-Controller (MVC) pattern called model-delegate, where the view and the controller of the MVC-pattern are merged into one object.
This pattern made the choice of labor division quite easy: all non-graphic parts of TangoATK reside in the packages beneath \texttt{fr.esrf.tangoatk.core}, and anything remotely graphic are located beneath \texttt{fr.esrf.tangoatk.widget}. More on the content and organization of this will follow.

The communication between the non-graphic and graphic objects are done by having the graphic object registering itself as a listener to the non-graphic object, and the non-graphic object emitting events telling the listeners that its state have changed.

### 7.2.1 Minimize development time

For TangoATK to help minimize the development time of graphic applications, the toolkit has been developed along two lines of thought:

- Things that are needed in most applications are included, eg \texttt{Splash}, a splash window which gives a graphical way for the application to show the progress of a long operation. The splash window is mostly used in the startup phase of the application.

- Building blocks provided by TangoATK should be easy to use and follow certain patterns, eg every graphic widget has a \texttt{setModel} method which is used to connect the widget with its non-graphic model.

In addition to this, TangoATK provides a framework for error handling, something that is often a time consuming task.

### 7.2.2 Minimize bugs in applications

Together with the Tango API, TangoATK takes care of most of the hard things related to programming with Tango. Using TangoATK the developer can focus on developing her application, not on understanding Tango.

### 7.2.3 Attributes and commands from different devices

To be able to create applications with attributes and commands from different devices, it was decided that the central objects of TangoATK were not to be the device, but rather the \texttt{attributes and the commands}. This will certainly feel a bit awkward at first, but trust me, the design holds.

For this design to be feasible, a structure was needed to keep track of the commands and attributes, so the \texttt{command-list and the attribute-list} was introduced. These two objects can hold commands and attributes from any number of devices.

### 7.2.4 Avoid code duplication

When writing applications for a control-system without a framework much code is duplicated. Anything from simple widgets for showing numeric values to error handling has to be implemented each time. TangoATK supplies a number of frequently used widgets along with a framework for
connecting these widgets with their non-graphic counterparts. Because of this, the developer only needs to write the glue - the code which connects these objects in a manner that suits the specified application.

## 7.3 The real getting started

Generally there are two kinds of end-user applications: Applications that only know how to treat one device, and applications that treat many devices.

### 7.3.1 Single device applications

Single device applications are quite easy to write, even with a gui. The following steps are required:

1. Instantiate an `AttributeList` and fill it with the attributes you want.
2. Instantiate a `CommandList` and fill it with the commands you want.
3. Connect the whole `AttributeList` with a list viewer and / or each individual attribute with an attribute viewer.
4. Connect the whole `CommandList` to a command list viewer and / or connect each individual command in the command list with a command viewer.

```java
package examples;

import javax.swing.JFrame;
import javax.swing.JMenuItem;
import javax.swing.JMenuBar;
import javax.swing.JMenu;

import java.awt.event.ActionListener;
```

The following program (FirstApplication) shows an implementation of the list mentioned above. It should be rather self-explanatory with the comments.
import java.awt.event.ActionEvent;
import java.awt.BorderLayout;
import fr.esrf.tangoatk.core.AttributeList;
import fr.esrf.tangoatk.core.ConnectionException;
import fr.esrf.tangoatk.core.CommandList;
import fr.esrf.tangoatk.widget.util.ErrorHistory;
import fr.esrf.tangoatk.widget.util.ATKGraphicsUtils;
import fr.esrf.tangoatk.widget.attribute<ScalarListViewer;
import fr.esrf.tangoatk.widget.command.CommandComboViewer;

public class FirstApplication extends JFrame
{
    JMenuBar menu; // So that our application looks
    AttributeList attributes; // The list that will contain our
    CommandList commands; // The list that will contain our
    ErrorHistory errorHistory; // A window that displays errors
    ScalarListViewer sListViewer; // A viewer which knows how to
    CommandComboViewer commandViewer; // A viewer which knows how to display
    String device; // The name of our device.

    public FirstApplication()
    {
        // The swing stuff to create the menu bar and its pulldown menus
        menu = new JMenuBar();
        JMenu fileMenu = new JMenu();
        fileMenu.setText("File");
        JMenu viewMenu = new JMenu();
        viewMenu.setText("View");
        JMenuItem quitItem = new JMenuItem();
        quitItem.setText("Quit");
        quitItem.addActionListener(new
            java.awt.event.ActionListener()
            {
                public void
                actionPerformed(ActionEvent evt)
                {quitItemActionPerpared(evt);}
            });
        fileMenu.add(quitItem);
        JMenuItem errorHistItem = new JMenuItem();
        errorHistItem.setText("Error History");
        errorHistItem.addActionListener(new
            java.awt.event.ActionListener()
            {
                }
public void
    actionPerformed(ActionEvent evt)
    {
        errHistItemActionPerformed(evt);
    }
});
viewMenu.add(errorHistItem);
menu.add(fileMenu);
menu.add(viewMenu);
//
// Here we create ATK objects to handle attributes, commands and errors.
// attributes = new AttributeList();
// commands = new CommandList();
// errorHistory = new ErrorHistory();
// device = "id14/eh3_mirror/1";
// slistViewer = new ScalarListViewer();
// commandViewer = new CommandComboViewer();
//
// A feature of the command and attribute list is that if you
// supply an errorlistener to these lists, they'll add that
// errorlistener to all subsequently created attributes or
// commands. So it is important to do this _before_ you
// start adding attributes or commands.
//
// attributes.addErrorListener(errorHistory);
// commands.addErrorListener(errorHistory);
//
// Sometimes we're out of luck and the device or the attributes
// are not available. In that case a ConnectionException is thrown.
// This is why we add the attributes in a try/catch
//
try
{

// Another feature of the attribute and command list is that they
// can add wildcard names, currently only '*' is supported.
// When using a wildcard, the lists will add all commands or
// attributes available on the device.
// attributes.add(device + "/*");
}
catch (ConnectionException ce)
{
    System.out.println("Error fetching " +
        "attributes from " +
        device + " " + ce);
}

//
// See the comments for attributelist
//
try {
    commands.add(device + "/*");
} catch (ConnectionException ce) {
    System.out.println("Error fetching " +
    "commands from " +
    device + " " + ce);
}

// Here we tell the scalarViewer what it’s to show. The
// ScalarListViewer loops through the attribute-list and picks out
// the ones which are scalars and show them.
// sListViewer.setModel(attributes);

// This is where the CommandComboViewer is told what it’s to
// show. It knows how to show and execute most commands.
//
// commandViewer.setModel(commands);

// add the menubar to the frame
//
setMenuBar(menu);

// Make the layout nice.
//
getContentPane().setLayout(new BorderLayout());
getContentPane().add(commandViewer, BorderLayout.NORTH);
getContentPane().add(sListViewer, BorderLayout.SOUTH);

// A third feature of the attributelist is that it knows how
// to refresh its attributes.
//
attributes.startRefresher();

// JFrame stuff to make the thing show.
//
pack();
ATKGraphicsUtils.centerFrameOnScreen(this); // ATK utility to center window show();
CHAPTER 7. TANGOATK PROGRAMMER’S GUIDE

```java
}

public static void main(String [] args)
{
    new FirstApplication();
}
public void quitItemActionPerformed(ActionEvent evt)
{
    System.exit(0);
}
public void errHistItemActionPerformed(ActionEvent evt)
{
    errorHistory.setVisible(true);
}
```

The program should look something like this (depending on your platform and your device)

![Image]

7.3.2 Multi device applications

Multi device applications are quite similar to the single device applications, the only difference is that it does not suffice to add the attributes by wildcard, you need to add them explicitly, like this:

```java
try
{
    // a StringScalar attribute from the device one
    attributes.add("jlp/test/1/att_cinq");
}
7.3.3 More on displaying attributes

So far, we’ve only considered scalar attributes, and not only that, we’ve also cheated quite a bit since we just passed the attribute list to the fr.esrf.tangoatk.widget.attribute.ScalarListViewer and let it do all the magic. The attribute list viewers are only available for scalar attributes (NumberScalarListViewer and ScalarListViewer). If you have one or several spectrum or image attributes you must connect each spectrum or image attribute to it’s corresponding attribute viewer individually. So let’s take a look at how you can connect individual attributes (and not a whole attribute list) to an individual attribute viewer (and not to an attribute list viewer).

7.3.3.1 Connecting an attribute to a viewer

Generally it is done in the following way:

1. You retrieve the attribute from the attribute list
2. You instantiate the viewer
3. You call the setModel method on the viewer with the attribute as argument.
4. You add your viewer to some panel

The following example (SecondApplication), is a Multi-device application. Since this application uses individual attribute viewers and not an attribute list viewer, it shows an implementation of the list mentioned above.

```java
package examples;

import javax.swing.JFrame;
import javax.swing.JMenuItem;
import javax.swing.JMenuBar;
import javax.swing.JMenuItem;

import java.awt.event.ActionListener;
import java.awt.event.ActionEvent;
import java.awt.BorderLayout;
import java.awt.Color;

import fr.esrf.tangoatk.core.AttributeList;
```
import fr.esrf.tangoatk.core.ConnectionException;
import fr.esrf.tangoatk.core.IStringScalar;
import fr.esrf.tangoatk.core.INumberSpectrum;
import fr.esrf.tangoatk.core.INumberImage;
import fr.esrf.tangoatk.widget.util.ErrorHistory;
import fr.esrf.tangoatk.widget.util.Gradient;
import fr.esrf.tangoatk.widget.util.ATKGraphicsUtils;
import fr.esrf.tangoatk.widget.attribute.NumberImageViewer;
import fr.esrf.tangoatk.widget.attribute.NumberSpectrumViewer;
import fr.esrf.tangoatk.widget.attribute.SimpleScalarViewer;
public class SecondApplication extends JFrame
{
    JMenuBar menu;
    AttributeList attributes;  // The list that will contain our attributes
    ErrorHistory errorHistory;  // A window that displays errors
    IStringScalar ssAtt;
    INumberSpectrum nsAtt;
    INumberImage niAtt;
    public SecondApplication()
    {
        // Swing stuff to create the menu bar and its pull-down menus
        menu = new JMenuBar();
        JMenu fileMenu = new JMenu();
        fileMenu.setText("File");
        JMenu viewMenu = new JMenu();
        viewMenu.setText("View");
        JMenuItem quitItem = new JMenuItem();
        quitItem.setText("Quit");
        quitItem.addActionListener(new java.awt.event.ActionListener()
        {
            public void actionPerformed(ActionEvent evt)
            {quitItemActionPerformed(evt);}
        });

        fileMenu.add(quitItem);
        JMenuItem errorHistItem = new JMenuItem();
        errorHistItem.setText("Error History");
        errorHistItem.addActionListener(new java.awt.event.ActionListener()
        {
            public void actionPerformed(ActionEvent evt)
            {errorHistItemActionPerformed(evt);}
        });

        viewMenu.add(errorHistItem);
        menu.add(fileMenu);
        menu.add(viewMenu);

        // Here we create TangoATK objects to view attributes and errors.
        //
        attributes = new AttributeList();
        errorHistory = new ErrorHistory();

        // We create a SimpleScalarViewer, a NumberSpectrumViewer and
        // a NumberImageViewer, since we already knew that we were
        // playing with a scalar attribute, a number spectrum attribute
CHAPTER 7. TANGOATK PROGRAMMER'S GUIDE

// and a number image attribute this time.

SimpleScalarViewer ssViewer = new SimpleScalarViewer();
NumberSpectrumViewer nSpectViewer = new NumberSpectrumViewer();
NumberImageViewer nImageViewer = new NumberImageViewer();
attributes.addErrorListener(errorHistory);

//
// The attribute (and command) list has the feature of returning the last
// attribute that was added to it. Just remember that it is returned as an
// IEntity object, so you need to cast it into a more specific object, like
// IStringScalar, which is the interface which defines a string scalar
//
try
{
    ssAtt = (IStringScalar) attributes.add("jlp/test/1/att_cinq");
nSAtt = (INumberSpectrum) attributes.add("jlp/test/1/att_spectrum");
niAtt = (INumberImage) attributes.add("sr/d-ipc/id25-1n/Image");
}
catch (ConnectionException ce)
{
    System.out.println("Error fetching one of the attributes "+" + ce);
    System.out.println("Application Aborted.");
    System.exit(0);
}

// Pay close attention to the following three lines!! This is how it's done!
// This is how it's always done! The setModel method of any viewer takes care
// of connecting the viewer to the attribute (model) it's in charge of displaying.
// This is the way to tell each viewer what (which attribute) it has to show.
// Note that we use a viewer adapted to each type of attribute

ssViewer.setModel(ssAtt);
nSpectViewer.setModel(nSAtt);
nImageViewer.setModel(niAtt);

nSpectViewer.setPreferredSize(new java.awt.Dimension(400, 300));
nImageViewer.setPreferredSize(new java.awt.Dimension(500, 300));
Gradient g = new Gradient();
g.buildColorGradient();
g.setColorAt(0, Color.black);
nImageViewer.setGradient(g);
nImageViewer.setBestFit(true);

//
// Add the viewers into the frame to show them

getContentPane().setLayout(new BorderLayout());
getContentPane().add(ssViewer, BorderLayout.SOUTH);
getContentPane().add(nSpectViewer, BorderLayout.CENTER);
getContentPane().add(nImageViewer, BorderLayout.EAST);

//
// To have the attributes values refreshed we should start the
// attribute list’s refresher.

attributes.startRefresher();
CHAPTER 7. TANGOATK PROGRAMMER'S GUIDE

```java
//
// add the menubar to the frame
//
setJMenuBar(menu);
//
// JFrame stuff to make the thing show.
//
pack();
ATKGraphicsUtils.centerFrameOnScreen(this); // ATK utility to center window show();
}
public static void main(String [] args)
{
    new SecondApplication();
}
public void quitItemImagePressed(ActionEvent evt)
{
    System.exit(0);
}
public void errHistItemImagePressed(ActionEvent evt)
{
    errorHistory.setVisible(true);
}
```

This program (SecondApplication) should look something like this (depending on your platform and your device attributes)

![Image of a program window](image)

### 7.3.3.2 Synoptic viewer

TangoATK provides a generic class to view and to animate the synoptics. The name of this class is fr.esrf.tangoatk.widget.jdraw.SynopticFileViewer. This class is based on a “home-made” graphical layer called jdraw. The jdraw package is also included inside TangoATK distribution.
SynopticFileViewer is a panel containing a TangoSynopticHandler instance. All the work for connection to tango devices and run time animation is done inside the TangoSynopticHandler.

The recipe for using the TangoATK synoptic viewer is the following:

1. You use Jdraw graphical editor to draw your synoptic.

2. During drawing phase don’t forget to associate parts of the drawing to tango devices, attributes or commands. Use the “name” property to do this.

3. During drawing phase you can also associate a class (frequently a “specific panel” class) which will be displayed when the user clicks on some part of the drawing. Use the “extension” property to do this.

4. Save the drawing file.

5. You can now develop a simple TangoATK based application which instantiates the SynopticFileViewer and gives it the name of the synoptic file (drawing file) and the directory where it resides.

The SynopticFileViewer will browse the objects in the synoptic file at run time. It discovers if some parts of the drawing is associated with a device, an attribute or a command. In this case it will automatically connect to the corresponding device, attribute or command. Once the connection is successful, SynopticFileViewer will animate the synoptic according to the default behaviour described below:

- For Tango devices: the colour of the drawing object reflects the state of the tango device. A mouse click on the drawing object associated with the tango device will instantiate and display the class specified during the drawing phase. If no class is specified the atkpanel generic device panel is displayed.

- For Tango attributes: the current value of the attribute is displayed through the drawing object.

- For Tango commands: the mouse click on the drawing object associated with the command will launch the device command.

- If the tooltip property is set to “name” when the mouse enters any Tango object (device, attribute or command), inside the synoptic drawing the name of the Tango object is displayed in a tooltip.

The following example (ThirdApplication), is a Synoptic application. We assume that the synoptic has already been drawn using Jdraw graphical editor.

```java
package examples;
import java.io.*;
import java.util.*;
import javax.swing.JFrame;
import javax.swing.JMenu;
import javax.swing.JMenuItem;
import javax.swing.JMenuBar;
import javax.swing.JMenuItem;
import java.awt.event.ActionListener;
import java.awt.event.ActionEvent;
import java.awt.BorderLayout;
import fr.esrf.tangoatk.widget.util.ErrorHistory;
import fr.esrf.tangoatk.widget.util.ATKGraphicsUtils;
```
import fr.esrf.tangoatk.widget.jdraw.SynopticFileViewer;
import fr.esrf.tangoatk.widget.jdraw.TangoSynopticHandler;
public class ThirdApplication extends JFrame {
    JMenuBar menu;
    ErrorHistory errorHistory; // A window that displays errors
    SynopticFileViewer sfv; // TangoATK generic synoptic viewer

    public ThirdApplication() {
        // Swing stuff to create the menu bar and its pulldown menus
        menu = new JMenuBar();
        JMenu fileMenu = new JMenu();
        fileMenu.setText("File");
        JMenu viewMenu = new JMenu();
        viewMenu.setText("View");
        JMenuItem quitItem = new JMenuItem();
        quitItem.setText("Quit");
        quitItem.addActionListener(new java.awt.event.ActionListener() {
            public void actionPerformed(ActionEvent evt) {
                quitItemActionPerformed(evt);
            }
        });
        fileMenu.add(quitItem);
        JMenuItem errorHistItem = new JMenuItem();
        errorHistItem.setText("Error History");
        errorHistItem.addActionListener(new java.awt.event.ActionListener() {
            public void actionPerformed(ActionEvent evt) {
                errorHistItemActionPerformed(evt);
            }
        });
        viewMenu.add(errorHistItem);
        menu.add(fileMenu);
        menu.add(viewMenu);
        // Here we create TangoATK synoptic viewer and error window.
        // errorHistory = new ErrorHistory();
        sfv = new SynopticFileViewer();
        try {
            sfv.setErrorWindow(errorHistory);
        } catch (Exception setErrwExcept) {
            System.out.println("Cannot set Error History Window");
        }
        // Here we tell the synoptic viewer where is located the synoptic file.
        // sfv.setJdrawDir("/users/ponce/ATK_QLD/jdraw_files");
    }
// Here we define the name of the synoptic file to show and the tooltip mode to use
//
try
{
sfv.setJdrawFileName("id14.jdw");
sfv.setToolTipMode(TangoSynopticHandler.TOOL_TIP_NAME);
}
catch (FileNotFoundException fnfEx)
{
    javax.swing.JOptionPane.showMessageDialog(null, "Cannot find the synoptic file : id14.jdw.\n" + "Check the file name you entered;" + " Application will abort ...");
    fnfEx
    "No such file",
    javax.swing.JOptionPane.ERROR_MESSAGE);
    System.exit(-1);
}
catch (IllegalArgumentException illEx)
{
    javax.swing.JOptionPane.showMessageDialog
    null, "Cannot parse the synoptic file : id14.jdw.\n" + "Check if the file is a Jdraw file." + " Application will abort ...");
    illEx,
    "Cannot parse the file",
    javax.swing.JOptionPane.ERROR_MESSAGE);
    System.exit(-1);
}
catch (MissingResourceException mrEx)
{
    javax.swing.JOptionPane.showMessageDialog
    null, "Cannot parse the synoptic file : id14.jdw.\n" + " Application will abort ...");
    mrEx,
    "Cannot parse the file",
    javax.swing.JOptionPane.ERROR_MESSAGE);
    System.exit(-1);
}
// Add the viewers into the frame to show them
//
getContentPane().setLayout(new BorderLayout());
getContentPane().add(sfv, BorderLayout.CENTER);
// add the menubar to the frame
//
setMenuBar(menu);
// JFrame stuff to make the thing show.
//
pack();
ATKGraphicsUtils.centerFrameOnScreen(this); //TangoATK utility to center window
show();
}
public static void main(String[] args)
{
    new ThirdApplication();
}
public void quitItemActionPerformed(ActionEvent evt)
{
    System.exit(0);
}
public void errHistItemActionPerfomed(ActionEvent evt)
{
    errorHistory.setVisible(true);
}
}

The synoptic application (ThirdApplication) should look something like this (depending on your synoptic drawing file)

7.3.4 A short note on the relationship between models and viewers

As seen in the examples above, the connection between a model and its viewer is generally done by calling setModel(model) on the viewer, it is never explained what happens behind the scenes when this is done.

7.3.4.1 Listeners

Most of the viewers implement some sort of listener interface, eg INumberScalarListener. An object implementing such a listener interface has the capability of receiving and treating events from a model which emits events.

    // this is the setModel of a SimpleScalarViewer
    public void setModel(INumberScalar scalar) {
        clearModel();
        if (scalar != null) {
            format = scalar.getProperty("format").getPresentation();
    }
CHAPTER 7. TANGOATK PROGRAMMER'S GUIDE

```
numberModel = scalar;

// this is where the viewer connects itself to the
// model. After this the viewer will (hopefully) receive
// events through its numberScalarChange() method
numberModel.addNumberScalarListener(this);

numberModel.getProperty("format").addPresentationListener(this);
numberModel.getProperty("unit").addPresentationListener(this);
```

```
// Each time the model of this viewer (the numberScalar attribute) decides it is time, it
// calls the numberScalarChange method of all its registered listeners
// with a NumberScalarEvent object which contains the
// the new value of the numberScalar attribute.
//
public void numberScalarChange(NumumberScalarEvent evt) {
    String val;
    val = getDisplayString(evt);
    if (unitVisible) {
        setText(val + " " + numberModel.getUnit());
    } else {
        setText(val);
    }
}
```

All listeners in Tango ATK implement the IErrorListener interface which specifies the errorChange(ChangeEvent e) method. This means that all listeners are forced to handle errors in some way or another.

7.4 The key objects of TangoATK

As seen from the examples above, the key objects of Tango ATK are the CommandList and the AttributeList. These two classes inherit from the abstract class AEntityList which implements all of the common functionality between the two lists. These lists use the functionality of the CommandFactory, the AttributeFactory, which both derive from AEntityFactory, and the DeviceFactory.

In addition to these factories and lists there is one (for the time being) other important functionality lurking around, the refresheres.

7.4.1 The Refreshers

The refresheres, represented in Tango ATK by the Refresher object, is simply a subclass of java.lang.Thread which will sleep for a given amount of time and then call a method refresh on whatever kind of IRefreshee it has been given as parameter, as shown below

```
// This is an example from DeviceFactory.
```
CHAPTER 7. TANGOATK PROGRAMMER’S GUIDE

// We create a new Refresher with the name "device"
// We add ourselves to it, and start the thread

Refresher refresher = new Refresher("device");
refresher.addRefresher(this).start();

Both the AttributeList and the DeviceFactory implement the IRefresher interface which specify only one method, refresh(), and can thus be refreshed by the Refresher. Even if the new release of TangoATK is based on the Tango Events, the refresher mechanism will not be removed yet. As a matter of fact, the method refresh() implemented in ATTRIBUTELIST skips all attributes (members of the list) for which the subscribe to the tango event has succeeded and calls the old refresh() method for the others (for which subscribe to tango events has failed). In a first stage this will allow the TangoATK applications to mix the use of the old tango devices servers (which do not implement tango events) and the new ones in the same code. In other words, TangoATK subscribes for tango events if possible otherwise TangoATK will refresh the attributes through the old refresher mechanism.

The AttributePolledList class allows the application programmer to force explicitly the use of the refresher method for all attributes added in an AttributePolledList even if the corresponding device servers implement tango events. Some viewers (fr.esrf.tangoatk.widget.attribute.Trend) needs an AttributePolledList in order to force the refresh of the attribute without using tango events.

7.4.1.1 What happens on a refresh

When refresh is called on the AttributeList and the DeviceFactory, they loop through their objects, IAttributes and IDevices, respectively, and ask them to refresh themselves if they are not event driven. When ATTRIBUTEFACTORY, respectively, DEVICEFACTORY creates an IAttribute / IDevice, TangoATK tries to subscribe for Tango Change event for that attribute (or device). If the subscription succeeds then the attribute (or device) is marked as event driven. In the refresh() method of the ATTRIBUTELIST and the DEVICEFACTORY during the loop through the objects if the object is marked event driven then the object is simply skipped. But if the object (attribute or device) is not marked as event driven, the refresh() method of the ATTRIBUTELIST, respectively, DEVICEFACTORY ask the object to refresh itself by calling the “refresh()” method of that object (attribute or device).

The refresh() method of an attribute will in turn call the “readAttribute” on the Tango device.

The result of this is that the IAttributes and the IDevices fire off events to their registered listeners containing snapshots of their state. The events are fired either because the IAttribute respectively IDevice has received a Tango Change event (event driven objects), or because the refresh() method of the object has issued a readAttribute on the Tango device.

7.4.2 The DeviceFactory

The device factory is responsible for two things

1. Creating new devices when needed
2. Refreshing the state and status of these devices

Regarding the first point, new devices are created when they are asked for and only if they have not already been created. If a programmer asks for the same device twice, she is returned a reference to the same device-object.

The DeviceFactory contains a Refresher as described above, which makes sure that the all Devices in the DeviceFactory updates their state and status and fire events to its listeners.
7.4.3 The AttributeFactory and the CommandFactory

These factories are responsible for taking a name of an attribute or command and returning an object representing the attribute or command. It is also responsible for making sure that the appropriate IDevice is already available. Normally the programmer does not want to use these factory classes directly. They are used by TangoATK classes indirectly when the application programmer calls the AttributeList's (or CommandList's) ADD() method.

7.4.4 The AttributeList and the CommandList

These lists are containers for attributes and commands. They delegate the construction-work to the factories mentioned above, and generally do not do much more, apart from containing refreshers, and thus being able to make the objects they contain refresh their listeners.

7.4.5 The Attributes

The attributes come in several flavors. Tango supports the following types:

- Short
- Long
- Double
- String
- Unsigned Char
- Boolean
- Unsigned short
- Float

The last four types (unsigned char, boolean, unsigned short and float) have been added to Tango since Tango 5. These types will be supported by TangoATK in the near future. According to Tango specifications, all these types can be of the following formats:

- Scalar, a single value
- Spectrum, a single array
- Image, a two dimensional array

For the sake of simplicity, TangoATK has combined all the numeric types into one, presenting all them all as doubles. So the TangoATK classes which handle the numeric attributes are : NumberScalar, NumberSpectrum and NumberImage (Number can be short, long, double, float, ...).

Again, to simplify things, there is no attribute class representing string-images as they are not likely to appear.

7.4.5.1 The hierarchy

As the observant reader will notice, a scalar is a spectrum with a length of one, which in fact is an image with a second dimension of length zero. From this observation the attribute hierarchy is expressed in the following interfaces:

INumberScalar which extends
CHAPTER 7. TANGOATK PROGRAMMER’S GUIDE  251

INumberSpectrum which extends
INumberImage which extends
IAttribute

The IStringScalar is left a bit on its own since it doesn’t cleanly follow the pattern mentioned above, so it extends IAttribute more or less directly.

Each of these types emit their proper events and have their proper listeners. Please consult the javadoc for further information.

7.4.6 The Commands

The commands in Tango are rather ugly beasts. There exists the following kinds of commands:

- Those which take input
- Those which do not take input
- Those which do output
- Those which do not do output

Now, for both input and output we have the following types:

- Double
- Float
- Unsigned Long
- Long
- Unsigned Short
- Short
- String

These types can appear in scalar or array formats. In addition to this, there are also four other types of parameters:

1. Boolean
2. Unsigned Char Array
3. The StringLongArray
4. The StringDoubleArray

The last two types mentioned above are two-dimensional arrays containing a string array in the first dimension and a long or double array in the second dimension, respectively.

As for the attributes, all numeric types have been converted into doubles, but there has been made little or no effort to create an hierarchy of types for the commands.
7.4.6.1 Events and listeners

The commands publish results to their IResultListeners, by the means of a ResultEvent. The IResultListener extends IErrorListener, any viewer of command-results should also know how to handle errors. So a viewer of command-results implements IResultListener interface and registers itself as a resultListener for the command it has to show the results.
Chapter 8

Writing a TANGO device server

8.1 The device server framework

This chapter will present the TANGO device server framework. It will introduce what is the device server pattern and then it will describe a complete device server framework. A definition of classes used by the device server framework is given in this chapter. This manual is not intended to give the complete and detailed description of classes data member or methods, refer to [8] to get this full description. But first, the naming convention used in this project is detailed.

The aim of the class definition given in this chapter is only to help the reader to understand how a TANGO device server works. For a detailed description of these classes (and their methods), refer to chapter 8.4 or to [8].

8.1.1 Naming convention and programming language

TANGO fully supports two different programming languages which are C++ and Java. When the Java code differs from the C++ code, examples in both languages will be given. For C++, its standard library has been used. Details about this library can be found in [9].

Every software project needs a naming convention. The naming convention adopted for the TDSOM is very simple and only defines two guidelines which are:

- Class names start with uppercase and use capitalization for compound words (For instance MyClassName).
- Method names are in lowercase and use underscores for compound words (For instance my_method_name).

These conventions will be use hereafter for both C++ and Java.

8.1.2 The device pattern

Device server are written using the Device pattern. The aim of this pattern is to provide the control programmer with a framework in which s/he can develop new control objects. The device pattern uses other design patterns like the Singleton and Command patterns. These patterns are fully described in [10]. The device pattern class diagram for stepper motor device is drawn in figure 8.1. In this figure, only classes surrounded with a dash line square are device specific. All the other classes are part of the TDSOM core and are developed by the Tango system team. Different kind of classes are used by the device pattern.

- Three of them are root classes and it is only necessary to inherit from them. These classes are the DeviceImpl, DeviceClass and Command classes.
Figure 8.1: Device pattern class diagram
• Classes necessary to implement commands. The TDSOM supports two ways to create command: Using inheritance or using the template command model. It is possible to mix model within the same device pattern

1. Using inheritance. This model of creating command heavily used the polymorphism offered by each modern object oriented programming language. In this schema, each command supported by a device via the command_inout or command_inout_async operation is implemented by a separate class. The Command class is the root class for each of these classes. It is an abstract class. A `execute` method must be defined in each sub-class. A `is_allowed` method may also be re-defined in each class if the default one does not fulfill all the needs\(^1\). In our stepper motor device server example, the DevReadPosition command follows this model.

2. Using the `template command` model. Using this model, it is not necessary to write one class for each command. You create one instance of classes already defined in the TDSOM for each command. The link between command name and method which need to be executed is done through pointers to method for C++ and through method names for Java. To support different kind of command, four classes are part of the TDSOM. These classes are:

   (a) The `TemplCommand` class for command without input or output parameter

   (b) The `TemplCommandIn` class for command with input parameter but without output parameter

   (c) The `TemplCommandOut` class for command with output parameter but without input parameter

   (d) The `TemplCommandInOut` class for all the remaining commands

• Classes necessary to implement TANGO device attributes. All these classes are part of the TANGO core classes. These classes are the `MultiAttribute`, `Attribute`, `WAttribute`, `Attr`, `SpectrumAttr` and `ImageAttr` classes. The last three are used to create user attribute. Each attribute supported by a device is implemented by a separate class. The Attr class is the root class for each of these classes. According to the attribute data format, the user class implementing the attribute must inherit from the Attr, SpectrumAttr or ImageAttr class. SpectrumAttr class inherits from Attr class and Image Attr class inherits from the SpectrumAttr class. The Attr base class defined three methods called `is_allowed`, `read` and `write`. These methods may be redefined in sub-classes in order to implement the attribute specific behaviour.

• The other are device specific. For stepper motor device, they are named StepperMotor, StepperMotorClass and DevReadPosition.

8.1.2.1 The `DeviceImpl` class

8.1.2.1.1 Description

This class is the device root class and is the link between the Device pattern and CORBA. It inherits from CORBA classes and implements all the methods needed to execute CORBA operations and attributes. For instance, its method `command_inout` is executed when a client requests a `command_inout` operation. The method `name` of the `DeviceImpl` class is executed when a client requests the name CORBA attribute. This class also encapsulates some key device data like its name, its state, its status, its black box... This class is an abstract class and cannot be instantiated as is.

\(^1\)The default `is_allowed` method behavior is to always allow the command
8.1.2.1.2 Contents

The contents of this class can be summarize as:

- Different constructors and one destructor
- Methods to access instance data members outside the class or its derivate classes. These methods are necessary because data members are declared as protected.
- Methods triggered by CORBA attribute request
- Methods triggered by CORBA operation request
- The init_device() method. This method makes the class abstract. It should be implemented by a sub-class. It is used by the inherited classes constructors.
- Methods triggered by the automatically added State and Status commands. These methods are declared virtual and therefore can be redefined in sub-classes. These two commands are automatically added to the list of commands defined for a class of devices. They are discussed in chapter 8.1.5
- A method called always_executed_hook() always executed for each command before the device state is tested for command execution. This method gives the programmer a hook where he/she can program some mandatory action which must be done before any command execution. An example of the such action is an hardware access to the device to read its real hardware state.
- A method called read_attr_data() triggered by the read attributes CORBA operation. This method is called once for each read_attributes call. This method is virtual and may be redefined in sub-classes.
- Methods for signal management (C++ specific)
- Data members like the device name, the device status, the device state
- Some private methods and data members

8.1.2.2 The DbDevice class

Each DeviceImpl instance is an aggregate with one instance of the DbDevice class. This DbDevice class can be used to query or modify device properties. It provides an easy to use interface for device objects in the database. The description of this class can be found in the Tango java or C++ API documentation.

8.1.2.3 The Command class

8.1.2.3.1 Description of the inheritance model

Within the TDSOM, each command supported by a device and implemented using the inheritance model is implemented by a separate class. The Command class is the root class for each of these classes. It is an abstract class. It stores the command name, the command argument types and description and mainly defines two methods which are the execute and is_allowed methods. The execute method should be implemented in each sub-class. A default is_allowed method exists for command always allowed. A command also stores a parameter which is the command display type. It is also used to select if the command must be displayed according to the application mode (every day operation or expert mode).
8.1.2.3.2 Description of the template model

Using this method, it is not necessary to create a separate class for each device command. In this method, each command is represented by an instance of one of the template command classes. They are four template command classes. All these classes inherits from the Command class. These four classes are:

1. The **TemplCommand** class. One object of this class must be created for each command without input or output parameters

2. The **TemplCommandIn** class. One object of this class must be created for each command without output parameter but with input parameter

3. The **TemplCommandOut** class. One object of this class must be created for each command without input parameter but with output parameter

4. The **TemplCommandInOut** class. One object of this class must be created for each command with input and output parameters

These four classes redefine the *execute* and *is_allowed* method of the Command class. These classes provides constructors which allow the user to:

- specify which method must be executed by these classes *execute* method
- optionally specify which method must be executed by these classes *is_allowed* method.

The method specification is done via pointer to method with C++ and simply with method name for java. Remember that it is possible to mix command implementation method within the same device pattern.

8.1.2.3.3 Contents

The content of this class can be summarizes as:

- Class constructors and destructor
- Declaration of the *execute* method
- Declaration of the *is_allowed* method
- Methods to read/set class data members
- Methods to extract data from the object used to transfer data on the network
- Methods to insert data into the object used to transfer data on the network
- Class data members like command name, command input data type, command input data description...

8.1.2.4 The DeviceClass class

8.1.2.4.1 Description

This class implements all what is specific for a controlled object class. For instance, every device of the same class supports the same list of commands and therefore, this list of available commands is stored in this DeviceClass. The structure returned by the info operation contains a documentation URL\(^2\). This documentation URL is the same for every device of the same class. Therefore, the

\(^2\) URL stands for Uniform Resource Locator
documentation URL is a data member of this class. There should have only one instance of this class per device pattern implementation. The device list is also stored in this class. It is an abstract class because the two methods `device_factory()` and `command_factory()` are declared as pure virtual. The rule of the `device_factory()` method is to create all the devices belonging to the device class. The rule of the `command_factory()` method is to create one instance of all the classes needed to support device commands. This class also stored the `attribute_factory` method. The rule of this method is to store in a vector of strings, the name of all the device attributes. This method has a default implementation which is an empty body for device without attribute.

8.1.2.4.2 Contents

The contents of this class can be summarize as:

- The `command_handler` method
- Methods to access data members.
- Signal related method (C++ specific)
- Class constructor. It is protected to implements the Singleton pattern
- Class data members like the class command list, the device list...

8.1.2.5 The DbClass class

Each DeviceClass instance is an aggregate with one instance of the DbClass class. This DbClass class can be used to query or modify class properties. It provides an easy to use interface for device objects in the database. The description of this class can be found in the Tango java or C++ API documentation.

8.1.2.6 The MultiAttribute class

8.1.2.6.1 Description

This class is a container for all the TANGO attributes defined for the device. There is one instance of this class for each device. This class is mainly an aggregate of Attribute object(s). It has been developed to ease TANGO attribute management.

8.1.2.6.2 Contents

The class contents could be summarizes as:

- Miscellaneous methods to retrieve one attribute object in the aggregate
- Method to retrieve a list of attribute with an alarm level defined
- Get attribute number method
- Miscellaneous methods to check if an attribute value is outside the authorized limits
- Method to add messages for all attribute with an alarm set
- Data members with the attribute list
8.1.2.7 The Attribute class

8.1.2.7.1 Description
There is one object of this class for each device attribute. This class is used to store all the attribute properties, the attribute value and all the alarm related data. Like commands, this class also stores the attribute display type. It is foreseen to be used by future Tango graphical application toolkit to select if the attribute must be displayed according to the application mode (every day operation or expert mode).

8.1.2.7.2 Contents
- Miscellaneous method to get boolean attribute information
- Methods to access some data members
- Methods to get/set attribute properties
- Method to check if the attribute is in alarm condition
- Methods related to attribute data
- Friend function to print attribute properties
- Data members (properties value and attribute data)

8.1.2.8 The WAttribute class

8.1.2.8.1 Description
This class inherits from the Attribute class. There is one instance of this class for each writable device attribute. On top of all the data already managed by the Attribute class, this class stores the attribute set value.

8.1.2.8.2 Contents
Within this class, you will mainly find methods related to attribute set value storage and some data members.

8.1.2.9 The Attr class

Within the TDSOM, each attribute supported by a device is implemented by a separate class. The Attr class is the root class for each of these classes. It is used in conjunction with the Attribute and WAttribute classes to implement Tango attribute behaviour. It defines three methods which are the is_allowed, read and write methods. A default is_allowed method exists for attribute always allowed. Default read and write empty methods are defined. For readable attribute, it is necessary to overwrite the read method. For writable attribute, it is necessary to overwrite the write method and for read and write attribute, both methods must be overwritten.

8.1.2.10 The SpectrumAttr class

This class inherits from the Attr class. It is the base class for user spectrum attribute. It is used in conjunction with the Attribute and WAttribute class to implement Tango spectrum attribute behaviour. From the Attr class, it inherits the Attr is_allowed, read and write methods.

8.1.2.11 The ImageAttr class

This class inherits from the SpectrumAttr class. It is the base class for user image attribute. It is used in conjunction with the Attribute and WAttribute class to implement Tango image attribute behaviour. From the Attr class, it inherits the Attr is_allowed, read and write methods.
8.1.2.12 The StepperMotor class

8.1.2.12.1 Description

This class inherits from the DeviceImpl class and is the class implementing the controlled object behavior. Each command will trigger a method in this class written by the device server programmer and specific to the object to be controlled. This class also stores all the device specific data.

8.1.2.12.2 Definition

```cpp
class StepperMotor: public DeviceImpl
{
public:
  StepperMotor(DeviceClass *, string &);
  StepperMotor(DeviceClass *, const char *);
  StepperMotor(DeviceClass *, const char *, const char *);
  ~StepperMotor() {};

  long dev_read_position(long);
  long dev_read_direction(long);
  bool direct_cmd_allowed(const CORBA::Any &);

  void read_attr_hardware(vector<long> &);
  bool is_Position_allowed(Tango::AttReqType);
  void read_Position(Tango::Attribute &);

  virtual Tango_DEVState dev_state();
  virtual Tango_DEVString dev_status();
  virtual void always_executed_hook();

  virtual void init_device();

protected:
  long axis[AGSM_MAX_MOTORS];
  long position[AGSM_MAX_MOTORS];
  long direction[AGSM_MAX_MOTORS];
  long state[AGSM_MAX_MOTORS];
};
```

Line 1: The StepperMotor class inherits from the DeviceImpl class
Line 4-7: Class constructors and destructor
Line 9: Method triggered by the DevReadPosition command
Line 10-11: Methods triggered by the DevReadDirection command
Line 13-15: Methods triggered by the reading of the Position attribute
Line 17: Redefinition of the dev_state method of the DeviceImpl class. This method will be triggered by the State command
Line 18: Redefinition of the dev_status method of the DeviceImpl class. This method will be triggered by the Status command
Line 19: Redefinition of the always_executed_hook method.
Line 21: Definition of the init_device method (declared as pure virtual by the DeviceImpl class)
8.1.2.13 The StepperMotorClass class

8.1.2.13.1 Description

This class inherits from the DeviceClass class. Like the DeviceClass class, there should be only one instance of the StepperMotorClass. This is ensured because this class is written following the Singleton pattern as defined in [10]. All controlled object class data which should be defined only once per class must be stored in this object.

8.1.2.13.2 Definition

1 class StepperMotorClass : public DeviceClass
2 {
3     public:
4         static StepperMotorClass *init(const char *);
5         static StepperMotorClass *instance();
6         "StepperMotorClass() {_instance = NULL;}
7     protected:
8         StepperMotorClass(string &);
9         static StepperMotorClass * _instance;
10         void command_factory();
11     private:
12         void device_factory(Tango_DevVarStringArray *);
13    };

---

Line 1: This class is a sub-class of the DeviceClass class
Line 4-5 and 9-10: Methods and data member necessary for the Singleton pattern
Line 6: Class destructor
Line 11: Definition of the command_factory method declared as pure virtual in the DeviceClass
Line 13-14: Definition of the device_factory method declared as pure virtual in the DeviceClass class

8.1.2.14 The DevReadPosition class

8.1.2.14.1 Description

This is the class for the DevReadPosition command. This class implements the execute and is_allowed methods defined by the Command class. This class is necessary because this command is implemented using the inheritance model.

8.1.2.14.2 Definition

1 class DevReadPositionCmd : public Command
2 {
3     public:
4         DevReadPositionCmd(const char *, Tango_CmdArgType, Tango_CmdArgType, const char *);
5  "DevReadPositionCmd() {};
6  virtual bool is_allowed (DeviceImpl *, const CORBA::Any &);
7  virtual CORBA::Any *execute (DeviceImpl *, const CORBA::Any &);
8  

Line 1: The class is a sub class of the Command class
Line 4-5: Class constructor and destructor
Line 7-8: Definition of the is_allowed and execute method declared as pure virtual in the Command class.

8.1.2.15 The PositionAttr class

8.1.2.15.1 Description
This is the class for the Position attribute. This attribute is a scalar attribute and therefore
inherits from the Attr base class. This class implements the read and is_allowed methods defined
by the Attr class.

8.1.2.15.2 Definition

1  class PositionAttr: public Tango::Attr
2  {
3  public:
4    PositionAttr():Attr("Position",Tango::DEV_LONG,Tango::READ);
5    "PositionAttr() {};
6  
7    virtual void read(Tango::DeviceImpl *dev,Tango::Attribute &att)
8    {
9      ((static_cast<StepperMotor *>(dev))->read_Position(att));
10     virtual bool is_allowed(Tango::DeviceImpl *dev,Tango::AttrReqType ty)
11     {return (static_cast<StepperMotor *>(dev))->is_Position_allowed(ty);} 
12  

Line 1: The class is a sub class of the Attr class
Line 4-5: Class constructor and destructor
Line 7: Re-definition of the read method defined in the Attr class. This is simply a "forward"
to the read_Position method of the StepperMotor class
Line 9: Re-definition of the is_allowed method defined in the Attr class. This is also a
"forward" to the is_Position_allowed method of the StepperMotor class

8.1.3 Startup of a device pattern
To start the device pattern implementation for stepper motor device, four methods of the StepperMotorClass class must be executed. These methods are:

1. The creation of the StepperMethodClass singleton via its init() method
2. The command_factory() method of the StepperMotorClass class
3. The attribute_factory() method of the StepperMotorClass class. This method has a default
   empty body for device class without attributes.
Figure 8.2: Device pattern startup sequence

4. The `device_factory()` method of the StepperMotorClass class

This startup procedure is described in figure 8.2. The creation of the StepperMotorClass will automatically create an instance of the DeviceClass class. The constructor of the DeviceClass class will create the Status, State and Init command objects and store them in its command list.

The `command_factory()` method will simply create all the user defined commands and add them in the command list.

The `attribute_factory()` method will simply build a list of device attribute names.

The `device_factory()` method will create each StepperMotor object and store them in the StepperMotorClass instance device list. The list of devices to be created and their names is passed to the `device_factory` method in its input argument. StepperMotor is a sub-class of DeviceImpl class. Therefore, when a StepperMotor object is created, a DeviceImpl object is also created. The DeviceImpl constructor builds all the device attribute object(s) from the attribute list built by the `attribute_factory()` method.

8.1.4 Command execution sequence

The figure 8.3
described how the method implementing a command is executed when a command_inout
CORBA operation is requested by a client. The command_inout method of the StepperMotor
object (inherited from the DeviceImpl class) is triggered by an instance of a class generated by the
CORBA IDL compiler. This method calls the command_handler() method of the StepperMotor-
Class object (inherited from the DeviceClass class). The command_handler method searches
in its command list for the wanted command (using its name). If the command is found, the al-
ways_executed_hook method of the StepperMotor object is called. Then, the is_allowed method
of the wanted command is executed. If the is_allowed method returns correctly, the execute
method is executed. The execute method extracts the incoming data from the CORBA object
use to transmit data over the network and calls the user written method which implements the
command.

8.1.5 The automatically added commands
In order to increase the common behavior of every kind of devices in a TANGO control system,
three commands are automatically added to each class of devices. These commands are:

- State
- Status
- Init

The default behavior of the method called by the State command depends on the device state. If
the device state is ON or ALARM, the method will:

- read the attribute(s) with an alarm level defined
- check if the read value is above/below the alarm level and eventually change the device state
to ALARM.
- returns the device state.
For all the other device state, the method simply returns the device state stored in the DeviceImpl class. Nevertheless, the method used to return this state (called dev_state) is defined as virtual and can be redefined in DeviceImpl sub-class. The difference between the default State command and the state CORBA attribute is the ability of the State command to signal an error to the caller by throwing an exception.

The default behavior of the method called by the Status command depends on the device state. If the device state is ON or ALARM, the method returns the device status stored in the DeviceImpl class plus additional message(s) for all the attributes which are in alarm condition. For all the other device state, the method simply returns the device status as it is stored in the DeviceImpl class. Nevertheless, the method used to return this status (called dev_status) is defined as virtual and can be redefined in DeviceImpl sub-class. The difference between the default Status command and the status CORBA attribute is the ability of the Status command to signal an error to the caller by throwing an exception.

The Init command is used to re-initialize a device without changing its network connection. This command calls the device delete_device method and the device init_device method. The rule of the delete_device method is to free memory allocated in the init_device method in order to avoid memory leak.

8.1.6 Reading/Writing attributes

8.1.6.1 Reading attributes

A Tango client is able to read Tango attribute(s) with the CORBA read_attributes call. Inside the device server, this call will trigger several methods of the device class (StepperMotor in our example):

1. The always_executed_hook() method.
2. A method call read_attr_hardware(). This method is called once per read_attributes CORBA call. The aim of this method is to read the device hardware and to store the result in a device class data member.
3. For each attribute to be read

   (a) A method called is_<att name>_allowed(). The rule of this method is to allow (or disallow) the next method to be executed. It is useful for device with some attributes which can be read only in some precise conditions. It has one parameter which is the request type (read or write).

   (b) A method called read_<att name>_(). The aim of this method is to extract the real attribute value from the hardware read-out and to store the attribute value into the attribute object. It has one parameter which is a reference to the Attribute object to be read.

The figure 8.4 is a drawing of these method calls sequencing. For attribute always readable, a default is_allowed method is provided. This method always returns true.
8.1.6.2 Writing attributes

A Tango client is able to write Tango attribute(s) with the CORBA write_attributes call. Inside a device server, this call will trigger several methods of the device class (StepperMotor in our example)

1. The always_executed_hook() method.
2. For each attribute to be written

   (a) A method called is_<att name>_allowed(). The rule of this method is to allow (or disallow) the next method to be executed. It is useful for device with some attributes which can be written only in some precise conditions. It has one parameter which is the request type (read or write).

   (b) A method called write_<att name>(). It has one parameter which is a reference to the WAttribute object to be written. The aim of this method is to get the data to be written from the WAttribute object and to write this value into the corresponding hardware.

The figure 8.5 is a drawing of these method calls sequencing. For attribute always writeable, a default is_allowed method is provided. This method always always returns true.
8.1.7 The device server framework

8.1.7.1 Vocabulary

A device server pattern implementation is embedded in a process called a device server. Several instances of the same device server process can be used in a TANGO control system. To identify instances, a device server process is started with an instance name which is different for each instance. The device server name is the couple device server executable name/device server instance name. For instance, a device server started with the following command

Perkin id11

starts a device server process with an instance name id11, an executable name Perkin and a device server name Perkin/id11.

8.1.7.2 The DServer class

In order to simplify device server process administration, a device of the DServer class is automatically added to each device server process. Thus, every device server process supports the same set of administration commands. The implementation of this DServer class follows the device pattern and therefore, its device behaves like any other devices. The device name is

dserver/device server executable name/device server instance name

For instance, for the device server process described in chapter 8.1.7.1, the dserver device name is dserver/perkin/id11. This name is the name returned by the adm_name CORBA attribute available for every device. On top of the three automatically added commands, this device supports the following commands:

- DevRestart
- RestartServer
- QueryClass
- QueryDevice
• Kill
• SetTraceLevel (Java server only)
• GetTraceLevel (Java server only)
• SetTraceOutput (Java server only)
• GetTraceOutput (Java server only)
• AddLoggingTarget (C++ server only)
• RemoveLoggingTarget (C++ server only)
• GetLoggingTarget (C++ server only)
• GetLoggingLevel (C++ server only)
• SetLoggingLevel (C++ server only)
• StopLogging (C++ server only)
• StartLogging (C++ server only)
• PolledDevice
• DevPollStatus
• AddObjPolling
• RemObjPolling
• UpdObjPollingPeriod
• StartPolling
• StopPolling
• EventSubscriptionChange

These commands will be fully described later in this document.

Several controlled object classes can be embedded within the same device server process and it is the rule of this device to create all these device server patterns and to call their command and device factories as described in 8.1.3. The name and number of all the classes to be created is known to this device after the execution of a method called class\_factory. With C++, it is the user responsibility to write this method. Using Java, this method is already written and automatically retrieves which classes must be created and creates them.

8.1.7.3 The Tango::Util class

8.1.7.3.1 Description

This class merges a complete set of utilities in the same class. It is implemented as a singleton and there is only one instance of this class per device server process. It is mandatory to create this instance in order to run a device server. The description of all the methods implemented in this class can be found in [8].
8.1.7.3.2 Contents

Within this class, you can find:

- Static method to create/retrieve the singleton object
- Miscellaneous utility methods like getting the server output trace level, getting the CORBA ORB pointer, retrieving device server instance name, getting the server PID and more. Please, refer to [8] to get a complete list of all these utility methods.
- Method to create the device pattern implementing the DServer class (server_init())
- Method to start the server (server_run())
- TANGO database related methods

8.1.7.4 A complete device server

Within a complete device server, at least two implementations of the device server pattern are created (one for the dserver object and the other for the class of devices to control). On top of that, one instance of the Tango::Util class must also be created. A drawing of a complete device server is in figure 8.6

8.1.7.5 Device server startup sequence

The device server startup sequence is the following:

1. Create an instance of the Tango::Util class. This will initialize the CORBA Object Request Broker
2. Called the `server_init` method of the `Tango::Util` instance. The call to this method will:

   (a) Create the DServerClass object of the device pattern implementing the DServer class. This will create the dserver object which during its construction will:

      i. Called the `class_factory` method of the DServer object. This method must create all the `xxxClass` instance for all the device pattern implementation embedded in the device server process.

      ii. Call the `command_factory` and `device_factory` of all the classes previously created. The list of devices passed to each call to the `device_factory` method is retrieved from the TANGO database.

3. Wait for incoming request with the `server_run()` method of the `Tango::Util` class.

### 8.2 Exchanging data between client and server

Exchanging data between clients and server means most of the time passing data between processes running on different computer using the network. Tango limits the type of data exchanged between client and server and defines a way to exchange these data. This chapter details these features. Memory allocation and error reporting are also discussed.

All the rules described in this chapter are valid only for data exchanged between client and server. For device server internal data, classical C++ or Java types can be used.

#### 8.2.1 Command data types

Commands have a fixed calling syntax - consisting of one input argument and one output argument. Arguments type must be chosen out of a fixed set of 19 data types. The following table details type name, code and the corresponding CORBA IDL types.

The type name used in the type name column of this table is the C++ name. In the IDL file, all the Tango definition are grouped in a IDL module named Tango. The IDL module maps to C++ namespace. Therefore, all the data type are parts of a namespace called Tango. For Java, the IDL module maps to Java package and name are not changed related to the IDL file.

<table>
<thead>
<tr>
<th>Type name</th>
<th>IDL type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Tango::DevBoolean</td>
<td>boolean</td>
</tr>
<tr>
<td>Tango::DevShort</td>
<td>short</td>
</tr>
<tr>
<td>Tango::DevLong</td>
<td>long</td>
</tr>
<tr>
<td>Tango::DevFloat</td>
<td>float</td>
</tr>
<tr>
<td>Tango::DevDouble</td>
<td>double</td>
</tr>
<tr>
<td>Tango::DevUShort</td>
<td>unsigned short</td>
</tr>
<tr>
<td>Tango::DevULong</td>
<td>unsigned long</td>
</tr>
<tr>
<td>Tango::DevString</td>
<td>string</td>
</tr>
<tr>
<td>Tango::DevVarCharArray</td>
<td>sequence of unsigned char</td>
</tr>
<tr>
<td>Tango::DevVarShortArray</td>
<td>sequence of short</td>
</tr>
<tr>
<td>Tango::DevVarLongArray</td>
<td>sequence of long</td>
</tr>
<tr>
<td>Tango::DevVarFloatArray</td>
<td>sequence of float</td>
</tr>
<tr>
<td>Tango::DevVarDoubleArray</td>
<td>sequence of double</td>
</tr>
<tr>
<td>Tango::DevVarUShortArray</td>
<td>sequence of unsigned short</td>
</tr>
<tr>
<td>Tango::DevVarULongArray</td>
<td>sequence of unsigned long</td>
</tr>
<tr>
<td>Tango::DevVarStringArray</td>
<td>sequence of string</td>
</tr>
<tr>
<td>Tango::DevVarLongStringArray</td>
<td>structure with a sequence of long and a sequence of string</td>
</tr>
</tbody>
</table>
The CORBA Interface Definition Language uses a type called sequence for variable length array. This sequence type is mapped differently according to the language used (C++ or Java). The Tango::DevUxxx types are used for unsigned types. The Tango::DevVarxxxxArray must be used when the data to be transferred are variable length array. The Tango::DevVarLongStringArray and Tango::DevVarDoubleStringArray are structures with two fields which are variable length array of long and variable length array of strings for the Tango::DevVarLongStringArray and variable length array of double and variable length array of string for the Tango::DevVarDoubleStringArray. The Tango::State type is used by the State command to return the device state.

8.2.1.1 Using command data types with C++

Unfortunately, the mapping between IDL and C++ was defined before the C++ class library had been standardized. This explains why the standard C++ string class or vector classes are not used in the IDL to C++ mapping.

TANGO commands argument types can be grouped on five groups depending on the IDL data type used. These groups are:

1. Data type using basic types (Tango::DevBoolean, Tango::DevShort, Tango::DevLong, Tango::DevFloat, Tango::DevDouble, Tango::DevUshort and Tango::DevULong)
2. Data type using strings (Tango::DevString type)
3. Data types using sequences (Tango::DevVarxxxxArray types except Tango::DevVarLongStringArray and Tango::DevVarDoubleStringArray)
4. Data types using structures (Tango::DevVarLongStringArray and Tango::DevVarDoubleStringArray types)
5. Data type using enumeration (Tango::DevState type)

In the following sub chapters, only summaries of the IDL to C++ mapping are given. For a full description of the C++ mapping, please refer to [2]

8.2.1.1.1 Basic types

For these types, the mapping between IDL and C++ is obvious and defined in the following table.

<table>
<thead>
<tr>
<th>Tango type name</th>
<th>IDL type</th>
<th>C++</th>
<th>typedef</th>
</tr>
</thead>
<tbody>
<tr>
<td>Tango::DevBoolean</td>
<td>boolean</td>
<td>CORBA::Boolean</td>
<td>unsigned char</td>
</tr>
<tr>
<td>Tango::DevShort</td>
<td>short</td>
<td>CORBA::Short</td>
<td>short</td>
</tr>
<tr>
<td>Tango::DevLong</td>
<td>long</td>
<td>CORBA::Long</td>
<td>long</td>
</tr>
<tr>
<td>Tango::DevFloat</td>
<td>float</td>
<td>CORBA::Float</td>
<td>float</td>
</tr>
<tr>
<td>Tango::DevDouble</td>
<td>double</td>
<td>CORBA::Double</td>
<td>double</td>
</tr>
<tr>
<td>Tango::DevUShort</td>
<td>unsigned short</td>
<td>CORBA::UShort</td>
<td>unsigned short</td>
</tr>
<tr>
<td>Tango::DevULong</td>
<td>unsigned long</td>
<td>CORBA::ULong</td>
<td>unsigned long</td>
</tr>
</tbody>
</table>
The types defined in the column named C++ should be used for a better portability. All these types are defined in the CORBA namespace and therefore their qualified names is CORBA::xxx.

### 8.2.1.1.2 Strings

Strings are mapped to char *. The use of new and delete for dynamic allocation of strings is not portable. Instead, you must use helper functions defined by CORBA (in the CORBA namespace). These functions are:

```cpp
char *CORBA::string_alloc(unsigned long len);
char *CORBA::string_dup(const char *);
void CORBA::string_free(char *);
```

These functions handle dynamic memory for strings. The string_alloc function allocates one more byte than requested by the len parameter (for the trailing 0). The function string_dup combines the allocation and copy. Both string_alloc and string_dup return a null pointer if allocation fails. The string_free function must be used to free memory allocated with string_alloc and string_dup. Calling string_free for a null pointer is safe and does nothing. The following code fragment is an example of the Tango::DevString type usage:

```cpp
1    Tango::DevString str = CORBA::string_alloc(5);
2    strcpy(str,"TANGO");
3
4    Tango::DevString str1 = CORBA::string_dup("Do you want to danse TANGO?");
5
6    CORBA::string_free(str);
7    CORBA::string_free(str1);
```

Line 1-2: TANGO is a five letters string. The CORBA::string_alloc function parameter is 5 but the function allocates 6 bytes.

Line 4: Example of the CORBA::string_dup function

Line 6-7: Memory deallocation

### 8.2.1.1.3 Sequences

IDL sequences are mapped to C++ classes that behave like vectors with a variable number of elements. Each IDL sequence type results in a separate C++ class. Within each class representing an IDL sequence types, you find the following method (only the main methods are related here):

1. Four constructors:
   (a) A default constructor which creates an empty sequence.
   (b) The maximum constructor which creates a sequence with memory allocated for at least the number of elements passed as argument. This does not limit the number of element in the sequence but only the way how memory is allocated to store element
   (c) A sophisticated constructor where it is possible to assign the memory used by the sequence with a preallocated buffer.
   (d) A copy constructor which does a deep copy
2. An assignment operator which does a deep copy

3. A length accessor which simply returns the current number of elements in the sequence

4. A length modifier which changes the length of the sequence (which is different than the number of elements in the sequence)

5. Overloading of the [] operator. The subscript operator [] provides access to the sequence element. For a sequence containing elements of type T, the [] operator is overloaded twice to return value of type T & and const T &. Insertion into a sequence using the [] operator for the const T & make a deep copy. Sequence are numbered between 0 and length()-1.

Note that using the maximum constructor will not prevent you from setting the length of the sequence with a call to the length modifier. The following code fragment is an example of how to use a Tango::DevVarLongArray type

```cpp
1  Tango::DevVarLongArray *mylongseq_ptr;
2  mylongseq_ptr = new Tango::DevVarLongArray();
3  mylongseq_ptr->length(4);
4  (*mylongseq_ptr)[0] = 1;
5  (*mylongseq_ptr)[1] = 2;
6  (*mylongseq_ptr)[2] = 3;
7  (*mylongseq_ptr)[3] = 4;
8  // (*mylongseq_ptr)[4] = 5;
9  CORBA::Long nb_elt = mylongseq_ptr->length();
10  mylongseq_ptr->length(5);
11  (*mylongseq_ptr)[4] = 5;
12  for (int i = 0; i < mylongseq_ptr->length(); i++)
13      cout << "Sequence elt " << i + 1 << " = " << (*mylongseq_ptr)[i] << endl;
```

Line 1: Declare a pointer to Tango::DevVarLongArray type which is a sequence of long
Line 2: Create an empty sequence
Line 3: Change the length of the sequence to 4
Line 5 - 8: Initialize sequence elements
Line 10: Oops!!! The length of the sequence is 4. The behavior of this line is undefined and may be a core can be dumped at run time
Line 12: Get the number of element actually stored in the sequence
Line 14-15: Grow the sequence to five elements and initialize element number 5
Line 17-18: Print sequence element
Another example for the Tango::DevVarStringArray type is given

```cpp
1  Tango::DevVarStringArray mystrseq(4);
2  mystrseq.length(4);
3  mystrseq[0] = CORBA::string_dup("Rock and Roll");
```
CHAPTER 8  WRITING A TANGO DEVICE SERVER

5          mystreq[1] = CORBA::string_dup("Bossa Nova");
6          mystreq[2] = CORBA::string_dup("Waltz");
7          mystreq[3] = CORBA::string_dup("Tango");
8          CORBA::Long nb_elt = mystreq.length();
9          for (int i = 0; i < mystreq.length(); i++)
10             cout << "Sequence elt " << i + 1 << " = " << mystreq[i] << endl;

Line 1 : Create a sequence using the maximum constructor
Line 2 : Set the sequence length to 4. This is mandatory even if you used the maximum
constructor.
Line 4-7 : Populate the sequence
Line 9 : Get how many strings are stored into the sequence
Line 11-12 : Print sequence elements.

8.2.1.1.4 Structures

Only two TANGO types are defined as structures. These types are the Tango::DevVarLongStringArray
and the Tango::DevVarDoubleStringArray. IDL structures map to C++ structures with corre-
sponding members. For the Tango::DevVarLongStringArray, the two members are named svalue
for the sequence of strings and lvalue for the sequence of longs. For the Tango::DevVarDoubleStringArray,
the two structure members are called svalue for the sequence of strings and dvalue for the sequence
of double. An example of the usage of the Tango::DevVarLongStringArray type is detailed below.

1          Tango::DevVarLongStringArray my_vl;
2          myvl.svalue.length(2);
3          myvl.svalue[0] = CORBA_string_dup("Samba");
4          myvl.svalue[1] = CORBA_string_dup("Rumba");
5          myvl.lvalue.length(1);
6          myvl.lvalue[0] = 10;

Line 1 : Declaration of the structure
Line 3-5 : Initialization of two strings in the sequence of string member
Line 7-8 : Initialization of one long in the sequence of long member

8.2.1.1.5 Enumeration

Only one TANGO type is an enumeration. This is the Tango::DevState type used to transfer device
state between client and server. IDL enumerated types map to C++ enumerations (amazing no?)
with a trailing dummy enumerator to force enumeration to be a 32 bit type. The first enumerator
will have the value 0, the next one will have the value 1 and so on.

1          Tango::DevState state;
2          state = Tango::ON;
3          state = Tango::FAULT;
8.2.1.2 Using command data types with Java

All the rules described in this chapter are valid only for data exchanged between client and server. For device server internal data, classical Java types can be used.

TANGO commands argument types can be grouped in four groups depending on the IDL data type used. These groups are:

1. Data type using basic types (DevBoolean, DevShort, DevLong, DevFloat, DevDouble, DevUShort, DevULong and DevString)
2. Data types using sequences (DevVarxxxxArray types except DevVarLongStringArray and DevVarDoubleStringArray)
3. Data types using structures (DevVarLongStringArray and DevVarDoubleStringArray types)
4. Data type using enumeration (DevState type)

In the following sub chapters, only summaries of the IDL to Java mapping are given. For a full description of the Java mapping, please refer to [12].

8.2.1.2.1 Basic types

For these types, the mapping between IDL and Java is obvious and defined in the following table.

<table>
<thead>
<tr>
<th>Tango type name</th>
<th>IDL type</th>
<th>Java type</th>
</tr>
</thead>
<tbody>
<tr>
<td>DevBoolean</td>
<td>boolean</td>
<td>boolean</td>
</tr>
<tr>
<td>DevShort</td>
<td>short</td>
<td>short</td>
</tr>
<tr>
<td>DevLong</td>
<td>long</td>
<td>int</td>
</tr>
<tr>
<td>DevFloat</td>
<td>float</td>
<td>float</td>
</tr>
<tr>
<td>DevDouble</td>
<td>double</td>
<td>double</td>
</tr>
<tr>
<td>DevString</td>
<td>string</td>
<td>String</td>
</tr>
<tr>
<td>DevUShort</td>
<td>unsigned short</td>
<td>short</td>
</tr>
<tr>
<td>DevULong</td>
<td>unsigned long</td>
<td>int</td>
</tr>
</tbody>
</table>

The Java int is a 32 bits type\(^3\) and therefore, the DevLong type maps to Java int. Java does not support unsigned types, this is why the DevUShort type maps to short and the DevULong type maps to int. In the contrary of C++, Java does not support a preprocessor and therefore, declaring a data from the DevLong type (or any other type in the previous table) will result in compiler errors. Instead, the Java types must be used.

IDL string maps directly to java.lang.String class.

8.2.1.2.2 Sequences

IDL sequences map to Java array. The following tables details the mapping used for Tango sequence types.

<table>
<thead>
<tr>
<th>Tango type name</th>
<th>IDL type</th>
<th>Java type</th>
</tr>
</thead>
</table>

\(^3\)The Java long type is a 64 bits data type
8.2.1.2.3 Structures

IDL structures map to a final Java class with the same name. This class provides instance variables for all IDL structure fields. It also provides a default constructor and a constructor from all structures fields values. The class name, the field name and types are summaries in the following table:

<table>
<thead>
<tr>
<th>Tango type name</th>
<th>Java class name</th>
<th>field name</th>
<th>field Java type</th>
</tr>
</thead>
<tbody>
<tr>
<td>DevVarLongStringArray</td>
<td>DevVarLongStringArray</td>
<td>lvalue</td>
<td>int[]</td>
</tr>
<tr>
<td></td>
<td></td>
<td>svalue</td>
<td>String[]</td>
</tr>
<tr>
<td>DevVarDoubleStringArray</td>
<td>DevVarDoubleStringArray</td>
<td>dvalue</td>
<td>double[]</td>
</tr>
<tr>
<td></td>
<td></td>
<td>svalue</td>
<td>String[]</td>
</tr>
</tbody>
</table>

8.2.1.2.4 Enumeration

Enumeration does not exist in Java. An IDL enumeration is mapped to a final class with the same name as the enum type. This class has the following members:

1. A value method which returns the value as an integer.
2. A pair of static data members per label.
   (a) The first one is an integer with a name equals to the label name prepended with an underscore ("_") like _ON for instance.
   (b) The second one is a reference to an object of the class representing the enumeration with its value set to the label value.
3. An integer conversion method called from_int which returns a reference to an object of the class representing the enumeration
4. A private constructor

The following code fragment is an example of Tango command data types usage
1 short l = 2;
2 String[] str_array = new String[2];
3 str_array[0] = new String("Be Bop");
4 str_array[1] = new String("Break dance");
5 System.out.println("Elt nb in DevVarStringArray data " + str_array.length);
6 for (int i = 0; i < str_array.length; i++)
7     System.out.println("Element value = " + str_array[i]);
8
9 DevVarLongStringArray ls = new DevVarLongStringArray();
10     ls.lvalue = new int[1];
11     ls.lvalue[0] = 1;
12     ls.svalue = new String[2];
13     ls.svalue[0] = new String("Smurf");
14     ls.svalue[1] = new String("Pogo");
15     DevState st = DevState.FAULT;
16     switch (st.value())
17         {  
18             case DevState._ON :
19                 System.out.println("The state is ON");
20                 st = DevState.FAULT;
21                 break;
22             case DevState._FAULT :
23                 System.out.println("The state is FAULT");
24                 st = DevState.ON;
25                 break;
26         }

Line 1 : Use of a DevShort type (pretty simple no)
Line 3-5 : Use of a DevVarStringArray data type with 2 elements
Line 7-9 : Print DevVarStringArray data element number and value
Line 11-16 : Use of a DevVarLongStringArray data type
Line 18 : Initialization of a DevState data with the FAULT state
Line 19 : Test on the DevState data value
Line 21 : Use the integer value associated to each enumeration label to test DevState data
Line 23 : Update DevState data value

8.2.2 Passing data between client and server

In order to have one definition of the CORBA operation used to send a command to a device whatever the command data type is, TANGO uses CORBA IDL any object. The IDL type any provides a universal type that can hold a value of arbitrary IDL types. Type any therefore allows you to send and receive values whose types are not fixed at compile time.

Type any is often compared to a void * in C. Like a pointer to void, an any value can denote a datum of any type. However, there is an important difference; whereas a void * denotes a completely untyped value that can be interpreted only with advance knowledge of its type, values of type any maintain type safety. For example, if a sender places a string value into an any, the receiver cannot extract the string as a value of the wrong type. Attempt to read the contents of an any as the wrong type cause a run-time error.
CHAPTER 8. WRITING A TANGO DEVICE SERVER

Internally, a value of type any consists of a pair of values. One member of the pair is the actual value contained inside the any and the other member of the pair is the type code. The type code is a description of the value’s type. The type description is used to enforce type safety when the receiver extracts the value. Extraction of the value succeeds only if the receiver extracts the value as a type that matches the information in the type code.

Within TANGO, the command input and output parameters are objects of the IDL any type. Only insertion/extraction of all types defined as command data types is possible into/from these any objects.

8.2.2.1 C++ mapping for IDL any type

The IDL any maps to the C++ class CORBA::Any. This class contains a large number of methods with mainly methods to insert/extract data into/from the any. It provides a default constructor which builds an any which contains no value and a type code that indicates “no value”. Such an any must be used for command which does not need input or output parameter.

The operator $<=$ is overloaded many times to insert data into an any object. The operator $=>$ is overloaded many times to extract data from an any object.

8.2.2.1.1 Inserting/Extracting TANGO basic types

The insertion or extraction of TANGO basic types is straightforward using the $<=$ or $=>$ operators. Nevertheless, the Tango::DevBoolean type is mapped to a unsigned char and other IDL types are also mapped to char C++ type (The unsigned is not taken into account in the C++ overloading algorithm). Therefore, it is not possible to use operator overloading for these IDL types which map to C++ char. For the Tango::DevBoolean type, you must use the CORBA::Any::from Boolean or CORBA::Any::to Boolean intermediate objects defined in the CORBA::Any class.

8.2.2.1.2 Inserting/Extracting TANGO strings

The $<=$ operator is overloaded for const char * and always makes a deep copy. This deep copy is done using the CORBA::string_dup function. The extraction of strings uses the $=>$ overloaded operator. The main point is that the Any object retains ownership of the string, so the returned pointer points at memory inside the Any. This means that you must not deallocate the extracted string and you must treat the extracted string as read-only.

8.2.2.1.3 Inserting/Extracting TANGO sequences

Insertion and extraction of sequences also uses the overloaded $<=$ and $=>$ operators. The insertion operator is overloaded twice: once for insertion by reference and once for insertion by pointer. If you insert a value by reference, the insertion makes a deep copy. If you insert a value by pointer, the Any assumes the ownership of the pointed-to memory.

Extraction is always by pointer. As with strings, you must treat the extracted pointer as read-only and must not deallocate it because the pointer points at memory internal to the Any.

8.2.2.1.4 Inserting/Extracting TANGO structures

This is identical to inserting/extracting sequences.

8.2.2.1.5 Inserting/Extracting TANGO enumeration

This is identical to inserting/extracting basic types

---

1 CORBA::Any a;
Tango::DevLong l1, l2;
l1 = 2;
a <<= l1;
a >>= 12;
CORBA::Any b;
Tango::DevBoolean b1, b2;
b1 = true;
b <<= CORBA::Any::from_boolean(b1);
b >>= CORBA::Any::to_boolean(b2);
CORBA::Any s;
Tango::DevString str1, str2;
str1 = "I like dancing TANGO";
s <<= str1;
s >>= str2;
// CORBA::string_free(str2);
// a <<= CORBA::string_dup("Oops");
CORBA::Any seq;
Tango::DevVarFloatArray fl_arr1;
fl_arr1.length(2);
fl_arr1[0] = 1.0;
fl_arr1[1] = 2.0;
seq <<= fl_arr1;
const Tango::DevVarFloatArray *fl_arr_ptr;
seq >>= fl_arr_ptr;
// delete fl_arr_ptr;

Line 1-5: Insertion and extraction of Tango::DevLong type
Line 7-11: Insertion and extraction of Tango::DevBoolean type using the CORBA::Any::from Boolean
and CORBA::Any::to Boolean intermediate structure
Line 13-17: Insertion and extraction of Tango::DevString type
Line 19: Wrong! You should not deallocate a string extracted from an any
Line 20: Wrong! Memory leak because the <<= operator will do the copy.
Line 22-29: Insertion and extraction of Tango::DevVarxxArray types. This is an insertion by
reference and the use of the <<= operator makes a deep copy of the sequence. Therefore, after
line 27, it is possible to deallocate the sequence
Line 31: Wrong! You should not deallocate a sequence extracted from an any

8.2.2.2 The insert and extract methods of the Command class

In order to simplify the insertion/extraction into/from Any objects, small helper methods have
been written in the Command class. The signatures of these methods are:

```
void extract(const CORBA::Any &, Tango type &);
CORBA::Any *insert(Tango type);
```
An extract method has been written for all Tango types. These method extract the data from the Any object passed as parameter and throw an exception if the Any data type is incompatible with the awaiting type. An insert method have been written for all Tango types. These method create an Any object, insert the data into the Any and return a pointer to the created Any. For Tango types mapped to sequences or structures, two insert methods have been written: one for the insertion from pointer and the other for the insertion from reference. For Tango strings, two insert methods have been written: one for insertion from a classical Tango::DevString type and the other from a const Tango::DevString type. The first one deallocate the memory after the insert into the Any object. The second one only inserts the string into the Any object.

The previous example can be rewritten using the insert/extract helper methods (We suppose that we can use the Command class insert/extract methods)

```
1 int Tango::DevLong l1,l2;
2 l1 = 2;
3 CORBA::Any *a_ptr = insert(l1);
4 extract(*a_ptr,l2);
5
6 int Tango::DevBoolean b1,b2;
7 b1 = true;
8 CORBA::Any *b_ptr = insert(b1);
9 extract(*b_ptr,b2);
10
11 Tango::DevString str1,str2;
12 str1 = "I like dancing TANGO";
13 CORBA::Any *s_ptr = insert(str1);
14 extract(*s_ptr,str2);
15
16 Tango::DevVarFloatArray fl_arr1;
17 fl_arr1.length(2);
18 fl_arr1[0] = 1.0;
19 fl_arr1[1] = 2.0;
20 insert(fl_arr1);
21 CORBA::Any *seq_ptr = insert(fl_arr1);
22 Tango::DevVarFloatArray *fl_arr_ptr;
23 extract(*seq_ptr,fl_arr_ptr);
```

Line 1-4: Insertion and extraction of Tango::DevLong type
Line 6-9: Insertion and extraction of Tango::DevBoolean type
Line 11-14: Insertion and extraction of Tango::DevString type
Line 16-23: Insertion and extraction of Tango::DevVarxxxArray types. This is an insertion by reference which makes a deep copy of the sequence. Therefore, after line 20, it is possible to deallocate the sequence in any order.

8.2.2.3 Java mapping for IDL any type

The IDL any maps to the Java class org.omg.CORBA.Any. This class has all the necessary methods to insert and extract instances of IDL native types (short, int, float, string...). The method name to insert native IDL types is insert_<type name> (insert_short(), insert_float(), insert_string()). They all take a reference to the element to be inserted as argument. The method name to extract basic types is extract_<type name> (extract_short(), extract_float() or
extract_string()). These extract methods do not need argument and return a reference to the extracted data. If the extraction operations have a mismatched type, the CORBA BAD_OPERATION exception is raised. An “any” object is constructed with the create _any() method of the CORBA “orb” object. This orb object represents the Object Request Broker. Within a Tango device server, you can retrieve it with a method of the TangoUtil class described in [8].

8.2.2.3.1 Inserting/Extracting TANGO basic types and strings

The insertion or extraction of TANGO basic types and strings is straightforward using the insert or extract methods provided by the org.omg.CORBA.Any class.

8.2.2.3.2 Inserting/Extracting TANGO sequences, structures or enumeration

The IDL to Java compiler generates Helper classes for all types defined in the IDL file. The generated class name is the name of the type followed by the suffix Helper (DevVarCharArrayHelper, DevLongHelper). Classes are generated even for types which directly map to native Java types. Several static methods needed to manipulate the type are supplied in these classes. These include “Any” insert and extract operations for the type. For a data type <typename>, the insert and extract method are:

- public static void insert(org.omg.CORBA.Any a, <typename> t) {...}
- public static <typename> extract(Any a) {...}

Such classes exists for all the TANGO data types. The following code fragment is an example of the insertion/extraction in/from Any object with Java.

```java
1   Any a = TangoUtil.instance().get_orb().create_any();
2   int 11 = 1;
3   a.insert_long(11);
4   int 12 = a.extract_long();
5
6   DevLongHelper.insert(a, 11);
7   int 13 = DevLongHelper.extract(a);
8
9   Any s = TangoUtil.instance().get_orb().create_any();
10  String str = new String("I like dancing TANGO");
11  s.insert_string(str);
12  String str_ex = s.extract_string();
13
14  DevStringHelper.insert(s, str);
15  String str_help = DevStringHelper.extract(s);
16
17  Any arr = TangoUtil.instance().get_orb().create_any();
18  int[] array = new int[2];
19  array[0] = 1;
20  array[1] = 2;
21  DevVarLongArrayHelper.insert(arr, array);
22  int[] array_ext = DevVarLongArrayhelper.extract(arr);
```

---

Line 1: Create an instance of the Any class.
CHAPTER 8. WRITING A TANGO DEVICE SERVER

Line 3 : Insert a DevLong data into the Any object. The method name is insert_long because this is a method to insert an IDL long type into the object even if the IDL long type maps to an int in Java.

Line 4 : Extract a DevLong type from the Any
Line 6-7 : Insert or Extract DevLong data type to/from the Any object using the Helper class.
Line 9-12 : Create an Any object and a DevString data. Insert and Extract this string into/from the Any using the method provided by the any object
Line 14-15 : Insert or Extract string into/from the Any using methods provided by the Helper class

Line 17-22 : The same thing for data of the DevVarLongArray type. Note that DevVarLongArray is not a basic IDL type and the Any class does not provide method to insert/extract data of this type into/from the Any. The use of the methods provided by the Helper class is mandatory in this case.

8.2.2.4 The insert and extract methods of the Command class for Java

In order to simplify the insertion/extraction into/from Any objects, small helper methods have been written in the Command class. The signatures of these methods are:

```java
1  <java type> extract_<Tango type_name>(Any);
2  Any insert(<Tango type>);
```

An extract method has been written for all Tango types. These method extract the data from the Any object passed as parameter and throw an exception if the Any data type is incompatible with the awaiting type. All these extract methods take the same input parameter and only differ in their return type which is not taken into account for method overloading. Therefore, the name of the method depends on the type of the data to be extracted. The following is some example of these method names and signatures:

- `int extract_DevLong(Any) throws DevFailed` for the DevLong type
- `int[] extract_DevVarULongArray(Any) throws DevFailed` for DevVarULongArray type
- `String[] extract_DevVarStringArray(Any) throws DevFailed` for DevVarStringArray

An insert method have been written for all Tango types. These method create an Any object, insert the data into the Any and return a pointer to the created Any. The previous example can be rewritten using the insert/extract helper methods (We suppose that we can use the Command class insert/extract methods)

```java
1  int 11 = 1;
2  Any a = insert(11);
3  int 12 = extract_DevLong(a);
4  
5  String str = new String("I like dancing TANGO");
6  Any s = insert(str);
7  String str_ex = extract_DevString(s);
8  
9  int[] array = new int[2];
10  array[0] = 1;
11  array[1] = 2;
12  Any arr = insert(array);
13  int[] array_ext = extract_DevVarLongArray(arr);
```
8.2.3 C++ memory management

The rule described here are valid for variable length command data types like Tango::DevString or all the Tango::DevVarLongArray types.

The method executing the command must allocate the memory used to pass data back to the client or use static memory (like buffer declares as object data member. If necessary, the ORB will deallocate this memory after the data have been sent to the caller. Fortunately, for incoming data, the method have no memory management responsibilities. The details about memory management given in this chapter assume that the insert/extract methods of the Tango::Command class are used and only the method in the device object is discussed.

8.2.3.1 For string

Example of a method receiving a Tango::DevString and returning a Tango::DevString is detailed just below

```cpp
1  Tango::DevString MyDev::dev_string(Tango::DevString argin)
2  {
3      Tango::DevString argout;
4      cout << "the received string is " << argin << endl;
5      string str("Am I a good Tango dancer ?");
6      argout = new char[str.size() + 1];
7      strcpy(argout,str.c_str());
8      return argout;
9  }
```

Note that there is no need to deallocate the memory used by the incoming string. Memory for the outgoing string is allocated at line 8, then it is initialized at the following line. The memory allocated at line 8 will be automatically freed by the usage of the Command::insert() method. Using this schema, memory is allocated/freed each time the command is executed. For constant string length, a statically allocated buffer can be used.

```cpp
1  Tango::ConstDevString MyDev::dev_string(Tango::DevString argin)
2  {
3      Tango::ConstDevString argout;
4      cout << "the received string is " << argin << endl;
5      argout = "Hello world";
6      return argout;
7  }
```
A Tango::ConstDevString data type is used. It is not a new data Tango data type. It has been introduced only to allow Command::insert() method overloading. The argout pointer is initialized at line 7 with memory statically allocated. In this case, no memory will be freed by the Command::insert() method. There is also no memory copy in the contrary of the previous example. A buffer defined as object data member can also be used to set the argout pointer.

8.2.3.2 For array/sequence

Example of a method returning a Tango::DevVarLongArray is detailed just below

```cpp
1  Tango::DevVarLongArray *MyDev::dev_array()
2  {
3      Tango::DevVarLongArray *argout = new Tango::DevVarLongArray();
4      long output_array_length = ...;
5      argout->length(output_array_length);
6      for (int i = 0; i < output_array_length;i++)
7          (*argout)[i] = i;
8  
9      return argout;
10  }
```

In this case, memory is allocated at line 3 and 6. Then, the sequence is populated. The sequence is created and returned using pointer. The Command::insert() method will insert the sequence into the CORBA::Any object using this pointer. Therefore, the CORBA::Any object will take ownership of the allocated memory. It will free it when it will be destroyed by the CORBA ORB after the data have been sent away. It is also possible to use a statically allocated memory and to avoid copying in the sequence used to returned the data. This is explained in the following example assuming a buffer of long data is declared as device data member and named buffer.

```cpp
1  Tango::DevVarLongArray *MyDev::dev_array()
2  {
3      Tango::DevVarLongArray *argout;
4      long output_array_length = ...;
5      argout = create_DevVarLongArray(buffer, output_array_length);
6      return argout;
7  }
```

At line 3 only a pointer to a DevVarLongArray is defined. This pointer is set at line 6 using the create_DevVarLongArray() method. This method will create a sequence using this buffer without memory allocation and with minimum copying. The Command::insert() method used here is the same than the one used in the previous example. The sequence is created in a way that the destruction of the CORBA::Any object in which the sequence will be inserted will not destroy the buffer. The following create_XXX methods are defined in the DeviceImpl class:
8.2.3.3 For string array/sequence

Example of a method returning a Tango::DevVarStringArray is detailed just below

```c++
1  Tango::DevVarStringArray *MyDev::dev_str_array()
2  {
3      Tango::DevVarStringArray *argout = new Tango::DevVarStringArray();
4
5      argout->length(3);
6      (*argout)[0] = CORBA::string_dup("Rumba");
7      (*argout)[1] = CORBA::string_dup("Waltz");
8      string str("Jerck");
9      (*argout)[2] = CORBA::string_dup(str.c_str());
10     return argout;
11  }
```

Memory is allocated at line 3 and 5. Then, the sequence is populated at lines 6, 7 and 9. The usage of the CORBA::string_dup function also allocates memory. The sequence is created and returned using pointer. The Command::insert() method will insert the sequence into the CORBA::Any object using this pointer. Therefore, the CORBA::Any object will take ownership of the allocated memory. It will free it when it will be destroyed by the CORBA ORB after the data have been sent away. For portability reason, the ORB uses the CORBA::string_free function to free the memory allocated for each string. This is why the corresponding CORBA::string_dup or CORBA::string_alloc function must be used to reserve this memory. It is also possible to use a statically allocated memory and to avoid copying in the sequence used to returned the data. This is explained in the following example assuming a buffer of pointer to char is declared as device data member and named int_buffer.

```c++
1  Tango::DevVarStringArray *DocDs::dev_str_array()
2  {
3      int_buffer[0] = "first";
4      int_buffer[1] = "second";
5
6      Tango::DevVarStringArray *argout;
7      argout = create_DevVarStringArray(int_buffer, 2);
8      return argout;
9  }
```
The intermediate buffer is initialized with statically allocated memory at lines 3 and 4. The returned sequence is created at line 7 with the `create_DevVarStringArray()` method. Like for classical array, the sequence is created in a way that the destruction of the CORBA::Any object in which the sequence will be inserted will not destroy the buffer.

### 8.2.3.4 For Tango composed types

Tango supports only two composed types which are Tango::DevVarLongStringArray and Tango::DevVarDoubleStringArray. These types are translated to C++ structure with two sequences. It is not possible to use memory statically allocated for these types. Each structure element must be initialized as described in the previous sub-chapters using the dynamically allocated memory case.

### 8.2.4 Reporting errors

Tango uses the C++ and Java try/catch plus exception mechanism to report errors. Two kinds of errors can be transmitted between client and server:

1. **CORBA system error.** These exceptions are raised by the ORB and indicates major failures (A communication failure, An invalid object reference...)

2. **CORBA user exception.** These kind of exceptions are defined in the IDL file. This allows an exception to contain an arbitrary amount of error information of arbitrary type.

**TANGO** defines one user exception called **DevFailed**. This exception is a variable length array of **DevError** type (a sequence of DevError). The DevError type is a four fields structure. These fields are:

1. A string describing the type of the error. This string replaces an error code and allows a more easy management of include files.

2. The error severity. It is an enumeration with the three values which are WARN, ERR or PANIC.

3. A string describing in plain text the reason of the error

4. A string describing the origin of the error

The Tango::DevFailed type is a sequence of DevError structures in order to transmit to the client what is the primary error reason when several classes are used within a command. The sequence element 0 must be the DevError structure describing the primary error. A method called `print_exception()` defined in the Tango::Except class prints the content of exception (CORBA system exception or Tango::DevFailed exception). Some static methods of the Tango::Except class called `throw_exception()` can be used to throw Tango::DevFailed exception. Some other static methods called `re_throw_exception()` may also be used when the user want to add a new element in the exception sequence and re-throw the exception. With Java, these functions are static methods of the Except class. Details on these methods can be found in [8].

### 8.2.4.1 Example of throwing exception using C++

This example is a piece of code from the `command_handler()` method of the DeviceImpl class. An exception is thrown to the client to indicate that the requested command is not defined in the command list.
```cpp
1 TangoSys_0MemStream o;
2 o << "Command " << command << " not found" << ends;
3 Tango::Except::throw_exception((const char *)"API_CommandNotFound",
4         o.str(),
5       (const char *)"DeviceClass::command_handler");
6
7 try
8 {
9     ..... 
10 }
11 catch (Tango::DevFailed &e)
12 {
13     TangoSys_0MemStream o;
14
15     o << "Command " << command << " not found" << ends;
16     Tango::Except::re_throw_exception(e,
17         (const char *)"API_CommandNotFound",
18         o.str(),
19       (const char *)"DeviceClass::command_handler");
20 }

Line 1: Build a memory stream. Use the TangoSys_MemStream because memory streams
are not managed the same way between Windows and Unix.
Line 3: Build the reason string in the memory stream.
Line 4-5: Throw the exception to client using one of the throw_exception static method of
the Except class. This throw_exception method used here allows the definition of the error type
string, the reason string and the origin string of the DevError structure. The remaining DevError
field (the error severity) will be set to its default value. Note that the first and third parameters
are casted to const char *.
Standard C++ defines that such a string is already a const char *
but the GNU C++ compiler (release 2.95) does not use this type inside its function overloading
but rather uses a char * which leads to calling the wrong function.
Line 13-22: Re-throw an already caught tango::DevFailed exception with one more element
in the exception sequence.

8.2.4.2 Example of throwing exception using Java
This example is a fragment of code from the command_handler() method of the DeviceImpl class.
An exception is thrown to the client to indicate that the requested command is not defined in the
command list.
```
```java
1 StringBuffer o = new StringBuffer("Command ");
2 o.append(command);
3 o.append(" not found");
4 5  
5  
6 Except.throw_exception("API_CommandNotFound",
7     o.toString(),
8       "DeviceClass.command_handler");
```
8.3 The Tango Logging Service

A first introduction about this logging service has been done in chapter 3.5.

The TANGO Logging Service (TLS) gives the user the control over how much information is actually generated and to where it goes. In practice, the TLS allows to select both the logging level and targets of any device within the control system.

8.3.1 Logging Targets

The TLS implementation allows each device logging requests to print simultaneously to multiple destinations. In the TANGO terminology, an output destination is called a logging target. Currently, targets exist for console, file and log consumer device.

CONSOLE: logs are printed to the console (i.e. the standard output),

FILE: logs are stored in a XML file. A rolling mechanism is used to backup the log file when it reaches a certain size (see below),

DEVICE: logs are sent to a device implementing a well known TANGO interface (see section A.7 for a definition of the log consumer interface). One implementation of a log consumer associated to a graphical user interface is available within the Tango package. It is called the LogViewer.

The device’s logging behavior can be control by adding and/or removing targets.

Note: When the size of a log file (for file logging target) reaches the so-called rolling-file-threshold (rft), it is backed up as "current_log_file_name" + "_1" and a new "current_log_file_name" is opened. Obviously, there is only one backup file at a time (i.e. any existing backup is destroyed before the current log file is backed up). The default threshold is 2Mb, the minimum is 500 Kb and the maximum is 20 Mb.

8.3.2 Logging Levels

Devices can be assigned a logging level. It acts as a filter to control the kind of information sent to the targets. Since, there are (usually) much more low level log statements than high level statements, the logging level also control the amount of information produced by the device. The TLS provides the following levels (semantic is just given to be indicative of what could be log at each level):

OFF: Nothing is logged

FATAL: A fatal error occurred. The process is about to abort

ERROR: An (unrecoverable) error occurred but the process is still alive
WARN: An error occurred but could be recovered locally
INFO: Provides information on important actions performed
DEBUG: Generates detailed information describing the internal behavior of a device

Levels are ordered the following way:

```
DEBUG < INFO < WARN < ERROR < FATAL < OFF
```

For a given device, a level is said to be enabled if it is greater or equal to the logging level assigned to this device. In other words, any logging request which level is lower than the device's logging level is ignored.

Note: The logging level can't be controlled at target level. The device's targets shared the same device logging level.

### 8.3.3 Sending TANGO Logging Messages

#### 8.3.3.1 Logging macros in C++

The TIS provides the user with easy to use C++ macros with `printf` and `stream` like syntax. For each logging level, a macro is defined in both styles:

- `LOG_` {FATAL, ERROR, WARN, INFO or DEBUG}
- `{FATAL, ERROR, WARN, INFO or DEBUG}_STREAM`

These macros are supposed to be used within the device's main implementation class (i.e. the class that inherits (directly or indirectly) from the Tango::DeviceImpl class). In this context, they produce logging messages containing the device name. In other words, they automatically identify the log source. Section 8.3.3.2 gives a trick to log in the name of device outside its main implementation class. Printf like example:

```
LOG_DEBUG("%d - Hello world", i);
```

Stream like example:

```
DEBUG_STREAM << "Hello world" << endl;
```

These two logging requests are equivalent. Note the double parenthesis in the printf version.

#### 8.3.3.2 C++ logging in the name of a device

A device implementation is sometimes spread over several classes. Since all these classes implement the same device, their logging requests should be associated with this device name. Unfortunately, the C++ logging macros can't be used because they are outside the device's main implementation class. The Tango::LogAdapter class is a workaround for this limitation.

Any method not member of the device's main implementation class, which send log messages associated to a device must be a member of a class inheriting from the Tango::LogAdapter class. Here is an example:
1 class MyDeviceActualImpl: public Tango::LogAdapter
2 {
3     public:
4         MyDeviceActualImpl(..., Tango::DeviceImpl *device, ...)
5         : Tango::LogAdapter(device)
6         {
7             ....
8         // The following log is associated to the device passed to the constructor
9         //
10         DEBUG_STREAM << "In MyDeviceActualImpl constructor" << endl;
11         ....
12         }
13     }
14 }
15 }

8.3.3.3 Logging in Java

In order to send a log from a device implementation method (i.e. a method of a class inheriting from `TangoDs::DeviceImpl`), the developer makes use of the `org.apache.log4j.Logger` instance which reference is returned by the `DeviceImpl.get_logger` method. The `org.apache.log4j.Logger.fatal, error, warn, info` and `debug` methods provide the actual logging features. See for more information about the Logger class. Here is an example of Logging usage with Java:

```java
public class myDevice extends DeviceImpl implements TangoConst
{
    ...

    public void init_device()
    {
        ...

        // A Debug log
        get_logger().debug("Initializing device " + get_name());

        try
        {
            // Initialization code
            String p = get_property("startup property");
            if (p == null)
            {
                get_logger().warn("No startup property defined for " + get_name());
                ....
            }
        } catch (Exception e)
        {
            // An error log
```
8.3.3.4 Logging in the name of a device with Java

Using Java, you can log in the name of a device from anywhere in your code as far as you get a reference to this device. Use the device get_logger public method to obtain its associated logger then proceed as described in 8.3.3.3.

8.4 Writing a device server

Writing a device server can be made easier by adopting the correct approach. This chapter will describe how to write a device server. It is divided into the following parts: understanding the device, defining device commands, choosing device state and writing the necessary classes. All along this chapter, examples will be given using the stepper motor device server. Writing a device server for our stepper motor example device means writing:

- The main function
- The class_factory method (only for C++ device server)
- The StepperMotorClass class
- The DevReadPositionCmd and DevReadDirectionCmd classes
- The PositionAttr, SetPositionAttr and DirectionAttr classes
- The StepperMotor class.

All these functions and classes will be detailed. The stepper motor device server described in this chapter supports 2 commands and 3 attributes which are:

- Command DevReadPosition implemented using the inheritance model
- Command DevReadDirection implemented using the template command model
- Attribute Position (position of the first motor). This attribute is readable and is linked with a writable attribute (called SetPosition). When the value of this attribute is requested by the client, the value of the associated writable attribute is also returned.
- Attribute SetPosition (writable attribute linked with the Position attribute). This attribute has some properties with user defined default value.
- Attribute Direction (direction of the first motor)

As the reader will understand during the reading of the following sub-chapters, the command and attributes classes (DevReadPositionCmd, DevReadDirectionCmd, PositionAttr, SetPositionAttr and DirectionAttr) are very simple classes. A tool called Pogo has been developed to automatically generate/maintain these classes and to write part of the code needed in the remaining one. See xx to know more on this Pogo tool.

In order to also give an example of how the database objects part of the Tango device pattern could be used, our device has two properties. These properties are of the Tango long data types and are named “Max” and “Min”.

```c++
26       get_logger().error("unknown exception caught");
27     }
28 }
29 ...
30 }
```
8.4.1 Understanding the device

The first step before writing a device server is to develop an understanding of the hardware to be programmed. The Equipment Responsible should have description of the hardware and its operating modes (manuals, spec sheets etc.). The Equipment Responsible must also provide specifications of what the device server should do. The Device Server Programmer should demand an exact description of the registers, alarms, interlocks and any timing constraints which have to be kept. It is very important to have a good understanding of the device interfacing before starting designing a new class.

Once the Device Server Programmer has understood the hardware the next important step is to define what is a logical device i.e. what part of the hardware will be abstracted out and treated as a logical device. In doing so the following points of the TDSOM should be kept in mind

- Each device is known and accessed by its ascii name.
- The device is exported onto the network to be imported by applications.
- Each device belongs to a class.
- A list of commands exists per device.
- Applications use the device server api to execute commands on a device.

The above points have to be taken into account when designing the level of device abstraction. The definition of what is a device for a certain hardware is primarily the job of the Device Server Programmer and the Applications Programmer but can also involve the Equipment Responsible. The Device Server Programmer should make sure that the Applications Programmer agrees with her definition of what is a device.

Here are some guidelines to follow while defining the level of device abstraction -

- **efficiency**, make sure that not a too fine level of device abstraction has been chosen. If possible group as many attributes together to form a device. Discuss this with the Applications Programmer to find out what is efficient for her application.

- **hardware independency**, one of the main reasons for writing device servers is to provide the Applications Programmer with a software interface as opposed to a hardware interface. Hide the hardware structure of the device. For example if the user is only interested in a single channel of a multichannel device then define each channel to be a logical device. The user should not be aware of hardware addresses or cabling details. The user is very often a scientist who has a physics-oriented world view and not a hardware-oriented world view. Hardware independency also has the advantage that applications are immune to hardware changes to the device.

- **object oriented world view**, another raison d’être behind the device server model is to build up an object oriented view of the world. The device should resemble the user’s view of the object as closely as possible. In the case of the ESRF’s beam lines for example, the devices should resemble beam line scientist’s view of the machine.

- **atomism**, each device can be considered like an atom - is a independent object. It should appear independent to the client even if behind the scenes it shares some hardware or software with other objects. This is often the case with multichannel devices where the user would like to see each channel as a device but it is obvious that the channels cannot be programmed completely independently. The logical device is there to hide or make transparent this fact. If it is impossible to send commands to one device without modifying another device then a single device should be made out the two devices.
• **tailored vs general**, one of the philosophies of the TDSOM is to provide tailored solutions. For example instead of writing one serial line class which treats the general case of a serial line device and leaving the device protocol to be implemented in the client the TDSOM advocates implementing a device class which handles the protocol of the device. This way the client only has to know the commands of the class and not the details of the protocol. Nothing prevents the device class from using a general purpose serial line class if it exists of course.

### 8.4.2 Defining device commands

Each device has a list of commands which can be executed by the application across the network or locally. These commands are the Application Programmer’s network knobs and dials for interacting with the device.

The list of commands to be implemented depends on the capabilities of the hardware, the list of sensible functions which can be executed at a distance and of course the functionality required by the application. This implies a close collaboration between the Equipment Responsible, Device Server Programmer and the Application Programmer.

When drawing up the list of commands particular attention should be paid to the following points

- **performance**, no single command should monopolize the device server for a long time (a nominal value for long is one second). Commands should be implemented in such a way that it executes immediately returning with a response. At best try to keep command execution time down to less than the typical overhead of an rpc call i.e. 30 milliseconds. This of course is not always possible e.g. a serial line device could require 100 milliseconds of protocol exchange. The Device Server Programmer should find the best trade-off between the users requirements and the devices capabilities. If a command implies a sequence of events which could last for a long time then implement the sequence of events in another thread - don’t block the device server.

- **robustness**, should be provided which allow the client to recover from error conditions and or do a warm startup.

#### 8.4.2.1 Standard commands

A minimum set of three commands exist for all devices. These commands are

- State which returns the state of a device
- Status which returns the status of the device as a formatted ascii string
- Init which re-initialize a device without changing its network connection

These commands have already been discussed in 8.1.5

### 8.4.3 Choosing device state

The device state is a number which reflects the availability of the device. To simplify the coding for generic application, a predefined set of states are supported by TANGO. This list has 14 members which are

```
State name
```
The names used here have obvious meaning.

8.4.4 Device server utilities to ease coding/debugging

The device server framework supports one in C++ and two set of utilities to ease the process of coding and debugging device server code. These utilities are:

1. The device server verbose option
2. The device server output redirection system (Java specific)

Using these two facilities avoids the usage of the classical "#ifdef DEBUG" style which makes code less readable.

8.4.4.1 The device server verbose option

Each device server supports a verbose option called -v. Four verbose levels are defined from 1 to 4. Level 4 is the most talkative one. If you use the -v option without specifying level, level 4 will be assumed.

Since Tango release 3, a Tango Logging Service has been introduced (detailed in chapter 8.3). This -v option set-up the logging service. If it used, it will automatically add a console target to all devices embedded within the device server process. Level 1 and 2 will set the logging level to all devices embedded within the device server to INFO. Level 3 and 4 will set the logging level to all devices embedded within the device server to DEBUG. All messages sent by the API layer are associated to the administration device.

Java specific: A device server started with output level n will print all the messages of level between 1 and n. For instance, if you start a device server using -v3 option, only the output for level 1,2 and 3 will be displayed. Output for level 4 will not be printed. If you don’t use the -v option, the output level is set to 0. By convention, level 3 and 4 are reserved for print message embedded into the Tango library. Level 1 and 2 are free for the user.

8.4.4.1.1 Choosing the output level using C++

In C++ device server, this feature is now implemented using the Tango Logging Service (TLS), see chapter 8.3 to get all details on this service.
8.4.4.1.2 Choosing the output level using Java

With Java, four static objects inside the Util class have been defined. These objects are called out1, out2, out3 and out4. These four objects support the println method exactly as the out object inside the System class does. The first object (out1) defines a message which should be printed only when output level 1 or more is requested. The second one (out2) defines a message which should be printed only when output level 2 or more is requested. The same philosophy is used for out3 and out4. The usage of these outx objects is the same than the classical out.

```java
1 Util.out3.println("What a nice dance");
2 Util.out3.println("What's its name?");
3 System.out.println("Its name is TANGO");
```

Line 1-2: The two questions are level 3 messages.
Line 4: This print will be printed whatever the print level is.

If this piece of code is part of a device server started with a -v2 option, only the message defined line 4 will be displayed. If the device server is started with a -v3, -v4 or -v option, the two messages defined at lines 1 and 2 will also be displayed.

8.4.4.1.3 Changing the output level at run time (Java specific)

It is possible to change the output level at run time. You do so using commands of the dserver device. These two commands are:

- SetTraceLevel. This command needs the new trace level as input parameter. Using this command supersedes the level requested at device server process command line
- GetTraceLevel. This command returns the actual trace level.

8.4.4.2 Device server output redirection (Java specific)

Two commands of the dserver device allow device server output redirection. These two commands are:

- SetTraceOutput. This command sets all the device server output used to print message to be redirected to a file. This command needs the complete file path as input parameter. The file is local to the computer where the device server process is running.
- GetTraceOutput. This command returns the name of the file used to redirect device server process output. If no SetTraceOutput command has been used prior to the execution of this command, it returns a special string ("Initial Output") to indicates that the output is still the output defines at process startup.

8.4.4.3 Java usage example

These two previously described features can ease device server debugging. Suppose a device server process is started with the following command line (UNIX command line)

```bash
Java -DTANGO_HOST=xxx Perkin/Perkin kl22 > /dev/null
```
CHAPTER 8. WRITING A TANGO DEVICE SERVER

This command line does not define any output level. Therefore the default output level is chosen (0) and no message are printed. Sending a SetTraceLevel command requesting level 4 and a SetTraceOutput command with a file name /tmp/server.out will make the device server sending all the output to the /tmp/server.out file without stopping the process. The inspection of the /tmp/server.out file will hopefully help to find the reason of the device server problem. When the output are not needed anymore, sending a SetTraceOutput command with the input parameter set to “Initial Output” followed by a SetTraceLevel command with a requested level of 0 will return the server to its original state.

8.4.4.4 C++ utilities to ease device server coding

Some utilities functions have been added in the C++ release to ease Tango device server development. These utilities allow the user to

- Init a C++ vector from a data of one of the Tango DevVarXXXArray data types
- Init a data of one of the Tango::DevVarxxxArray data type from a C++ vector
- Print a data of one of Tango::DevVarxxxArray data type

They mainly used the “< <” operator overloading features. The following code lines are an example of usage of these utilities.

```cpp
1   vector<string> v1;
2   v1.push_back("one");
3   v1.push_back("two");
4   v1.push_back("three");
5
6   Tango::DevVarStringArray s;
7     s << v1;
8   cout << s << endl;
9
10  vector<string> v2;
11   v2 << s;
12
13   for (int i = 0; i < v2.size(); i++)
14       cout << "vector element = " << v2[i] << endl;
```

Line 1-4: Create and Init a C++ string vector
Line 7: Init a Tango::DevVarStringArray data from the C++ vector
Line 8: Print all the Tango::DevVarStringArray element in one line of code.
Line 11: Init a second empty C++ string vector with the content of the Tango::DevVarStringArray
Line 13-14: Print vector element

**Warning**: Note that due to a strange behavior of the Windows VC++ compiler compared to other compilers, to use these utilities with the Windows VC++ compiler, you must add the line “using namespace tango” at the beginning of your source file.

8.4.5 Avoiding name conflicts

8.4.5.1 Using C++

Namespace are used to avoid name conflicts. Each device pattern implementation is defined within its own namespace. The name of the namespace is the device pattern class name. In our example, the namespace name is `StepperMotor`.
8.4.5.2 Using Java

Package are used to avoid name conflicts. Each device pattern implementation is defined within its own package. The name of the package is the device pattern class name. In our example, the package name is StepperMotor.

8.4.6 The device server main function

A device server main function (or method) always follows the same framework. It exactly implements all the action described in chapter 8.1.7.5. Even if it could be always the same, it has not been included in the library because some linkers are perturbed by the presence of two main functions.

8.4.6.1 Using C++

```cpp
#include <tango.h>

int main(int argc, char *argv[])
{
    Tango::Util *tg;

    try
    {
        tg = Tango::Util::init(argc,argv);
        tg->server_init();
        cout << "Ready to accept request" << endl;
        tg->server_run();
    }
    catch (bad_alloc)
    {
        cout << "Can't allocate memory!!!" << endl;
        cout << "Exiting" << endl;
    }
    catch (CORBA::Exception &e)
    {
        Tango::Exception::print_exception(e);
        cout << "Received a CORBA::Exception" << endl;
        cout << "Exiting" << endl;
    }
    tg->server_cleanup();
    return(0);
}
```

Line 1: Include the `tango.h` file. This file is a master include file. It includes several other files. The list of files included by `tango.h` can be found in [8]
Line 11: Create the instance of the Tango::Util class (a singleton). Passing argc,argv to this method is mandatory because the device server command line is checked when the Tango::Util object is constructed.

Line 13: Start all the device pattern creation and initialization with the server_init() method

Line 16: Put the server in an endless waiting loop with the server_run() method. In normal case, the process should never returns from this line.

Line 18-22: Catch all exceptions due to memory allocation error, display a message to the user and exit

Line 23: Catch all standard TANGO exception which could occur during device pattern creation and initialization

Line 25: Print exception parameters

Line 27-28: Print an additional message

Line 31: Cleanup the server before exiting by calling the server_cleanup() method.

### 8.4.6.2 Using Java

The main method can be defined in any class. There is no mandatory class where it should be defined. In our StepperMotor example, the main method has been implemented in the StepperMotor class because it is the most logical place.

```java
1  package StepperMotor
2  
3  import java.util.*;
4  import org.omg.CORBA.*;
5  import fr.earf.Tango.*;
6  import fr.earf.TangoDs. *
7  
8  public class StepperMotor extends DeviceImpl implements TangoConst
9  {
10     public static void main(String[] argv)
11     {
12         try
13         {
14             Util tg = Util.init(argv,"StepperMotor");
15             tg.server_init();
16             System.out.println("Ready to accept request");
17             tg.server_run();
18         }
19         catch (OutOfMemoryError ex)
20             {
21                 System.err.println("Can’t allocate memory !!!!!");
22                 System.err.println("Exiting");
23             }
24         catch (UserException ex)
25             {
26                 Exception.print_exception(ex);
27             }
28         System.err.println("Received a CORBA user exception");
29     }
30 }
31 ```
CHAPTER 8. WRITING A TANGO DEVICE SERVER

33 System.err.println("Exiting");
34 }
35 catch (SystemException ex)
36 {
37     Exception.printStackTrace(ex);
38     System.err.println("Received a CORBA system exception");
39     System.err.println("Exiting");
40 }
41 System.exit(-1);
42 }
43 }
4 void Tango::DServer::class_factory()
5 {
6
7    add_class(StepperMotor::StepperMotorClass::init("StepperMotor");
8
9 }

Line 1 : Include the Tango master include file
Line 2 : Include the steppermotorclass class definition file
Line 7 : Create the StepperMotorClass singleton by calling its init method and stores the
returned pointer into the DServer object. Remember that all classes for the device pattern imple-
mentation for the stepper motor class is defined within a namespace called StepperMotor.

8.4.8 Writing the StepperMotorClass class
8.4.8.1 Using C++
8.4.8.1.1 The class definition file

1 #include <tango.h>
2
3 namespace StepperMotor
4 {
5
6   class StepperMotorClass : public Tango::DeviceClass
7   {
8      public:
9        static StepperMotorClass *init(const char *);
10        static StepperMotorClass *instance();
11        ~StepperMotorClass() {_instance = NULL;}
12
13      protected:
14        StepperMotorClass(string &);
15        static StepperMotorClass *instance;
16        void command_factory();
17        void attribute_factory(vector<Tango::Attr *> &);
18
19      public:
20        void device_factory(const Tango::DevVarStringArray *);
21   }
22
23 } /* End of StepperMotor namespace */

Line 1 : Include the Tango master include file
Line 3 : This class is defined within the StepperMotor namespace
Line 6 : Class StepperMotorClass inherits from Tango::DeviceClass
Line 9-10 : Definition of the init and instance methods. These methods are static and can be
called even if the object is not already constructed.
Line 11: The destructor
8.4.8.1.2 The singleton related methods

```cpp
#include <tango.h>

#include <steppermotor.h>
#include <steppermotorclass.h>

namespace StepperMotor
{
  StepperMotorClass *StepperMotorClass::_instance = NULL;

  StepperMotorClass::StepperMotorClass(string &s):
  Tango::DeviceClass(s)
  {
    INFO_STREAM << "Entering StepperMotorClass constructor" << endl;
    INFO_STREAM << "Leaving StepperMotorClass constructor" << endl;
  }

  StepperMotorClass *StepperMotorClass::init(const char *name)
  {
    if (_instance == NULL)
    {
      try
      {
        string s(name);
        _instance = new StepperMotorClass(s);
      }
      catch (bad_alloc)
      {
        throw;
      }
    }
    return _instance;
  }

  StepperMotorClass *StepperMotorClass::instance()
  {
    if (_instance == NULL)
    {
```
41    cerr << "Class is not initialised !!" << endl;
42    exit(-1);
43  }
44    return _instance;
45 }

Line 1-4: Include files: the Tango master include file (tango.h), the StepperMotorClass class
definition file (steppermotorclass.h) and the StepperMotor class definition file (steppermotor.h)

Line 6: Open the StepperMotor namespace.

Line 9: Initialize the static _instance field of the StepperMotorClass to NULL

Line 11-18: The class constructor. It takes an input parameter which is the controlled device
name. This parameter is passed to the constructor of the DeviceClass class. Otherwise, the
constructor does nothing except printing a message

Line 20-35: The init method. This method needs an input parameter which is the controlled
device class name (StepperMotor in this case). This method checks if the instance is already
constructed by testing the _instance data member. If the instance is not constructed, it creates
one. If the instance is already constructed, the method simply returns a pointer to it.

Line 37-43: The instance method. This method is very similar to the init method except that
if the instance is not already constructed, the method print a message and abort the process.

As you can understand, it is not possible to construct more than one instance of the Stepper-
MotorClass (it is a singleton) and the init method must be called prior to any other method.

8.4.8.1.3 The commandFactory method

Within our example, the stepper motor device supports two commands which are called DevRead-
Position and DevReadDirection. These two command takes a Tango::DevLong argument as input
and output parameter. The first command is created using the inheritance model and the second
command is created using the template command model.

1
2 void StepperMotorClass::command_factory()
3 {
4    command_list.push_back(new DevReadPositionCmd("DevReadPosition",
5      Tango::DEV_LONG,
6      Tango::DEV_LONG,
7      "Motor number (0-7)",
8      "Motor position"));
9
10   command_list.push_back(
11       new TemplateCommandInOut<Tango::DevLong, Tango::DevLong>
12         ((const char *)"DevReadDirection",
13          static_cast<Tango::Long_MethPtr_Lg>
14           (&StepperMotor::dev_read_direction),
15          static_cast<Tango::StateMethPtr>
16           (&StepperMotor::direct_cmd_allowed))
17         );
18  }
CHAPTER 8. WRITING A TANGO DEVICE SERVER

Line 4: Creation of one instance of the DevReadPositionCmd class. The class is created with five arguments which are the command name, the command type code for its input and output parameters and two strings which are the command input and output parameters description. The pointer returned by the new C++ keyword is added to the vector of available command.

Line 10-14: Creation of the object used for the DevReadDirection command. This command has one input and output parameter. Therefore the created object is an instance of the TemplCommandInOut class. This class is a C++ template class. The first template parameter is the command input parameter type, the second template parameter is the command output parameter type. The second TemplCommandInOut class constructor parameter (set at line 13) is a pointer to the method to be executed when the command is requested. A casting is necessary to store this pointer as a pointer to a method of the DeviceImpl class. The third TemplCommandInOut class constructor parameter (set at line 15) is a pointer to the method to be executed to check if the command is allowed. This is necessary only if the default behavior (command always allowed) does not fulfill the needs. A casting is necessary to store this pointer as a pointer to a method of the DeviceImpl class. When a command is created using the template command method, the input and output parameters type are determined from the template C++ class parameters.

8.4.8.1.4 The device_factory method

The device_factory method has one input parameter. It is a pointer to Tango::DevVarStringArray data which is the device name list for this class and the instance of the device server process. This list is fetch from the Tango database.

1 void StepperMotorClass::device_factory(const Tango::DevVarStringArray *devlist_ptr)
2 {
3     for (long i = 0; i < devlist_ptr->length(); i++)
4         {
5             DEBUG_STREAM << "Device name : " << (*devlist_ptr)[i] << endl;
6             device_list.push_back(new StepperMotor(this,
7                 (*devlist_ptr)[i]));
8             if (Tango::Util::_UseDb == true)
9                 export_device(device_list.back());
10             else
11                 export_device(device_list.back(),(*devlist_ptr[i]));
12         }
13     }

Line 4: A loop for each device.
Line 8: Create the device object using a StepperMotor class constructor which needs two arguments. These two arguments are a pointer to the StepperMotorClass instance and the device name. The pointer to the constructed object is then added to the device list vector.
Line 11-14: Export device to the outside world using the export_device method of the DeviceClass class.

The StepperMotor class inherits from the DeviceImpl class and therefore is a DeviceImpl.
8.4.8.15 The attribute_factory method

The rule of this method is to fulfill a vector of pointer to attributes. A reference to this vector is passed as argument to this method.

```cpp
1    void StepperMotorClass::attribute_factory(vector<Tango::Attr *> &att_list) 2    { 3        att_list.push_back(new PositionAttr()); 4 5        Tango::UserDefaultAttrProp def_prop; 6        def_prop.set_label("Set the motor position"); 7        def_prop.set_format("scientific;setprecision(4)"); 8        Tango::Attr *at = new SetPositionAttr(); 9        at->set_default_properties(def_prop); 10       att_list.push_back(at); 11 12       att_list.push_back(new DirectionAttr()); 13    }
```

Line 3: Create the PositionAttr class and store the pointer to this object into the attribute pointer vector.

Line 5-7: Create a Tango::UserDefaultAttrProp instance and set the label and format properties default values in this object.

Line 8: Create the SetPositionAttr attribute.

Line 9: Set attribute user default value with the set_default_properties() method of the Tango::Attr class.

Line 10: Store the pointer to this object into the attribute pointer vector.

Line 12: Create the DirectionAttr class and store the pointer to this object into the attribute pointer vector.

Please note that in some rare case, it is necessary to add attribute to this list during the device server life cycle. This attribute_factory() method is called once during device server start-up. A method add_attribute() of the DeviceImpl class allows the user to add a new attribute to the attribute list outside of this attribute_factory() method. See [8] for more information on this method.

8.4.8.2 Using Java

8.4.8.2.1 The singleton related method

```java
1    package StepperMotor;
2    import java.util.*;
3    import fr.earf.Tango.*;
4    import fr.earf.TangoDs.*;
5    public class StepperMotorClass extends DeviceClass implements TangoConst
6    { 7        private static StepperMotorClass _instance = null;
8    }
```
public static StepperMotorClass instance()
{
    if (_instance == null)
    {
        System.err.println("StepperMotorClass is not initialised !!
        System.err.println("Exiting");
        System.exit(-1);
    }
    return _instance;
}

public static StepperMotorClass init(String class_name) throws DevFailed
{
    if (_instance == null)
    {
        _instance = new StepperMotorClass(class_name);
    }
    return _instance;
}

protected StepperMotorClass(String name) throws DevFailed
{
    super(name);
    Util.out2.println("Entering StepperMotorClass constructor");
    Util.out2.println("Leaving StepperMotorClass constructor");
}

---

Line 1: This class is part of the StepperMotor package.
Line 3-5: Import different packages. The first one (java.lang.util) is a classical Java package
from the JDK. The second one (fr.esrf.Tango) is the package generated by the IDL compiler
from the Tango IDL file. The last one (fr.esrf.TangoDs) is the name of the package with all the
root classes of the device server framework.
Line 7: The StepperMotorClass inherits from the DeviceClass and implements the TangoConst
interface. The TangoConst interface does not define any method but simply defines
constant variables. The TangoConst interface is a member of the TangoDs package.
Line 9: The instance pointer. It is static and private. It is initialized to NULL
Line 12-21: The instance method. This method is very similar to the init method except that
if the instance is not already constructed, the method print a message and abort the process.
Line 24-31: The init method. This method needs an input parameter which is the controlled
device class name (StepperMotor in this case). This method checks if the instance is already
constructed by testing the _instance data member. If the instance is not constructed, it creates
one. If the instance is already constructed, the method simply returns a pointer to it.
Line 33-40: The class constructor which is protected. It takes an input parameter which is
the controlled device class name. This parameter is passed to the constructor of the DeviceClass
class (line 35). Otherwise, the constructor does nothing except printing a message.

As you can understand, it is not possible to construct more than one instance of the Stepper-
MotorClass (it is a singleton) and the init method must be called prior to any other method.
8.4.8.2.2 The command_factory method

Within our example, the stepper motor device supports two commands which are called DevReadPosition and DevReadDirection. These two commands take a Tango_DeviceLong argument as input and output parameter. The first command is created using the inheritance model and the second command is created using the template command model.

```java
1 public void command_factory()
2 {
3     String str = new String("DevReadPosition");
4     command_list.addElement(new DevReadPositionCmd(str,
5         Tango_DEV_LONG, Tango_DEV_LONG,
6         "Motor number (0-7)",
7         "Motor position");
8     str = new String("DevReadDirection");
9     command_list.addElement(new TemplCommandInOut(str,
10        "dev_read_direction",
11        "direct_cmd_allowed");
12 }
```

Line 4: Creation of one instance of the DevReadPositionCmd class. The class is created with five arguments which are the command name, the command type code for its input and output parameters and the parameters description (input and output). The Tango_DEV_LONG constant is defined in the TangoConst interface. The reference returned by the new Java keyword is added to the vector of available command via the `addElement` method of the Java Vector class.

Line 10-12: Creation of the object used for the DevReadDirection command. This command has one input and output parameter. Therefore the created object is an instance of the TemplCommandInOut class. The second TemplCommandInOut class constructor parameter (set at line 11) is the method name to be executed when the command is requested. The third TemplCommandInOut class constructor parameter (set at line 12) is the method name to be executed to check if the command is allowed. This is necessary only if the default behavior (command always allowed) does not fulfill the needs. When a command is created using the template command method, the input and output parameter types are determined from the given method declaration.

8.4.8.2.3 The device_factory method

The `device_factory` method has one input parameter. It is a pointer to a DevVarStringArray data which is the device name list for this class and the instance of the device server process. This list is fetched from the Tango database.

```java
1 public void device_factory(String[] devlist) throws DevFailed
2 {
3     for (int i = 0; i < devlist.length; i++)
4         {
5             Util.out4.println("Device name : " + devlist[i]);
6         }
7     device_list.addElement(new StepperMotor(this,
```

5DevVarStringArray maps to Java String[]
CHAPTER 8. WRITING A TANGO DEVICE SERVER

8  devlist[i],
9  "A Tango motor",
10  DevState.ON,
11  "The motor is ON"));
12  
13  if (Util.instance()._UseDb == true)
14     export_device(((DeviceImpl)(device_list.lastElement())));
15  else
16     export_device(((DeviceImpl)(device_list.lastElement())),
17     devlist[i]);
18  }

Line 3: A loop for each device
Line 7: Create the device object using a StepperMotor class constructor which needs five arguments. These five arguments are a reference to the StepperMotorClass instance, the device name, the device description, the device original state and the device original status. The reference to the constructed object is then added to the device list vector with the addElement method of the java.util.Vector class.
Line 13-17: Export device to the outside world using the export_device method of the DeviceClass class. The lastElement method of the java.util.Vector class returns a reference to an object of the java Object class. It must be casted before being passed to the export_device method

8.4.8.2.4 The attribute_factory method

The rule of this method is to fulfill a vector of references to attribute. A reference to this vector is passed to this method. The Tango core classes will use this vector to build all the attributes related objects (An instance of the MultiAttribute class and one Attribute or WAttribute object for each attribute defined in this vector).

1  public void attribute_factory(Vector att) throws DevFailed
2  {
3      att.addElement(new Attr("Position",
4           Tango_DEV_LONG,
5           AttrWriteType.READ_WITH_WRITE,
6           "SetPosition"));
7      
8      UserDefaultAttrProp def_prop = new UserDefaultAttrProp();
9      def_prop.set_label("set the motor position");
10     def_prop.set_format("scientific; setprecision(4)");
11     Attr at = new Attr("SetPosition",
12           Tango_DEV_LONG,
13           AttrWriteType.WRITE));
14     at.set_default_properties(def_prop);
15     att.addElement(at);
16      
17      att.addElement(new Attr("Direction",
18           Tango_DEV_LONG));
19  }
CHAPTER 8. WRITING A TANGO DEVICE SERVER

Line 3-6: Build a one dimension attribute of TANGO_DEV_LONG type with an associate writable attribute. Store a reference to this attribute in the vector. In this example, the attribute display type is not defined in the Attr class constructor. Therefore, it will be initialized with its default value (OPERATOR). Several Attr class constructors are defined with or without the attribute display type. See [8] for a complete constructor list.

Line 8-10: Create a UserDefaultAttrProp instance and set the label and format properties default values in this object.

Line 11-13: Build a one dimension writable attribute.

Line 14: Set attribute user default value with the set_default_properties() method of the Tango::Attr class.

Line 15: Store the reference to this attribute object into the attribute vector.

Line 17-18: Build a one dimension attribute. Store the reference to this attribute object into the attribute vector.

Please, note that in some rare case, it is necessary to add attribute to this list during the device server life cycle. This attribute_factory() method is called once during device server start-up. A method add_attribute() of the DeviceImpl class allows the user to add a new attribute to the attribute list outside of this attribute_factory() method. See [8] for more information on this method.

8.4.9 The DevReadPositionCmd class

8.4.9.1 Using C++

8.4.9.1.1 The class definition file

```c++
1 #include <tango.h>
2
3 namespace StepperMotor
4 {
5
6 class DevReadPositionCmd : public Tango::Command
7 {
8 public:
9     DevReadPositionCmd(const char *, Tango::CmdArgType,
10                        Tango::CmdArgType,
11                        const char *, const char *);
12     ~DevReadPositionCmd() {};
13
14     virtual bool is_allowed (Tango::DeviceImpl *, const CORBA::Any &);
15     virtual CORBA::Any *execute (Tango::DeviceImpl *, const CORBA::Any &);
16 );
17
18 } /* End of StepperMotor namespace */
```

Line 1: Include the tango master include file

Line 3: Open the StepperMotor namespace.

Line 6: The DevReadPositionCmd class inherits from the Tango::Command class

Line 9: The constructor

Line 12: The destructor

Line 14: The definition of the is_allowed method. This method is not necessary if the default behavior implemented by the default is_allowed method fulfill the requirements. The default behavior is to always allows the command execution (always return true).
8.4.9.1.2 The class constructor

The class constructor does nothing. It simply invoke the Command constructor by passing it its five arguments which are:

1. The command name
2. The command input type code
3. The command output type code
4. The command input parameter description
5. The command output parameter description

With this 5 parameters command class constructor, the command display level is not specified. Therefore it is set to its default value (OPERATOR). If the command does not have input or output parameter, it is not possible to use the Command class constructor defined with five parameters. In this case, the command constructor execute the Command class constructor with three elements (class name, input type, output type) and set the input or output parameter description fields with the set_in_type_desc or set_out_type_desc Command class methods. To set the command display level, it is possible to use a 6 parameters constructor or it is also possible to set it in the constructor code with the set_disp_level method. Many Command class constructors are defined. See [8] for a complete list.

8.4.9.1.3 The is_allowed method

In our example, the DevReadPosition command is allowed only if the device is in the ON state. This method receives two argument which are a pointer to the device object on which the command must be executed and a reference to the command input Any object. This method returns a boolean which must be set to true if the command is allowed. If this boolean is set to false, the DeviceClass command_handler method will automatically send an exception to the caller.

```cpp
bool DevReadPositionCmd::is_allowed(Tango::DeviceImpl *device,
const CORBA::Any &in_any)
{
    if (device->get_state() == Tango::ON)
        return true;
    else
        return false;
}
```

Line 4: Call the get_state method of the DeviceImpl class which simply returns the device state
Line 5: Authorize command if the device state is ON
Line 7: Refuse command execution in all other cases.

8.4.9.1.4 The execute method

This method receives two arguments which are a pointer to the device object on which the command must be executed and a reference to the command input Any object. This method returns a pointer to an any object which must be initialized with the data to be returned to the caller.
1    CORBA::Any *DevReadPositionCmd::execute(
2                Tango::DeviceImpl *device,
3                const CORBA::Any &in_any)
4    {
5        INFO_STREAM << "DevReadPositionCmd::execute(): arrived" << endl;
6        Tango::DevLong motor;
7        extract(in_any,motor);
8        return insert(
9                       (static_cast<StepperMotor *>(device))->dev_read_position(motor));
10    }

Line 8: Extract incoming data from the input any object using a Command class extract helper method. If the type of the data in the Any object is not a Tango::DevLong, the extract method will throw an exception to the client.

Line 9: Call the stepper motor object method which execute the DevReadPosition command and insert the returned value into an allocated Any object. The Any object allocation is done by the insert method which return a pointer to this Any.

8.4.9.2 Using Java

8.4.9.2.1 The class constructor

The class constructor does nothing. It simply invoke the Command constructor by passing it its five arguments which are:

1. The command name
2. The command input type code
3. The command output type code
4. The command input parameter description
5. The command output parameter description

With this 5 parameters command class constructor, the command display level is not specified. Therefore it is set to its default value (OPERATOR). If the command does not have input or output parameter, it is not possible to use the Command class constructor defined with five parameters. In this case, the command constructor execute the Command class constructor with three elements (class name, input type, output type) and set the input or output parameter description fields with the set_in_type_desc or set_out_type_desc Command class methods. To set the command display level, it is possible to use a 6 parameters constructor or it is also possible to set it in the constructor code with the set_disp_level method. Many Command class constructors are defined. See \[8\] for a complete list.

8.4.9.2.2 The is_allowed method

In our example, the DevReadPosition command is allowed only if the device is in the ON state. This method receives two argument which are a reference to the device object on which the command must be executed and a reference to the command input Any object. This method returns a boolean which must be set to true if the command is allowed. If this boolean is set to false, the DeviceClass command_handlers method will automatically send an exception to the caller.
```java
package StepperMotor;

import org.omg.CORBA.*;
import fr.ersf.Tango.*;
import fr.ersf.TangoDs.*;

public class DevReadPositionCmd extends Command implements TangoConst {
    public boolean is_allowed(DeviceImpl dev, Any data_in) {
        if (dev.get_state() == DevState.ON)
            return(true);
        else
            return(false);
    }
}
```

---

8.4.9.2.3 The execute method

This method receives two arguments which are a reference to the device object on which the command must be executed and a reference to the command input Any object. This method returns a reference to an any object which must be initialized with the data to be returned to the caller.

```java
public Any execute(DeviceImpl device, Any in_any) throws DevFailed {
    Util.out2.println("DevReadPositionCmd.execute(): arrived");
    int motor = extract_DevLong(in_any);
    return insert(((StepperMotor)(device)).dev_read_position(motor));
}
```
CHAPTER 8  WRITING A TANGO DEVICE SERVER

Line 5: Extract incoming data from the input any object
Line 7: Call the stepper motor object method which execute the DevReadPosition command, insert its return value into an any and return.

8.4.10 The PositionAttr class
8.4.10.1 Using C++
8.4.10.1.1 The class definition file

```cpp
#include <tango.h>
#include <steppermotor.h>

namespace StepperMotor
{

class PositionAttr: public Tango::Attr
{
  public:
    PositionAttr():Attr("Position",
          Tango::DEV_LONG,
          Tango::READ_WITH_WRITE,
          "SetPosition") {};
    ~PositionAttr() {}
;
    virtual void read(Tango::DeviceImpl *dev,Tango::Attribute &att)
    {
      if(static_cast<StepperMotor *>(dev))->read_Position(att);
    }
  virtual bool is_allowed(Tango::DeviceImpl *dev,Tango::AttrReqType ty)
    { return (static_cast<StepperMotor*>(dev))->is_Position_allowed(ty); }
};

} /* End of StepperMotor namespace */

#endif // _STEPPERMOTORCLASS_H
```

Line 1-2: Include the tango master include file and the steppermotor class definition include file
Line 4: Open the StepperMotor namespace.
Line 8: The PositionAttr class inherits from the Tango::Attr class
Line 11-14: The constructor with 4 arguments
Line 15: The destructor
Line 17: The definition of the read method. This method forwards the call to a StepperMotor class method called read_Position()
Line 19: The definition of the is_allowed method. This method is not necessary if the default behaviour implemented by the default is_allowed method fulfills the requirements. The default behaviour is to always allows the attribute reading (always return true). This method forwards the call to a StepperMotor class method called is_Position_allowed()
8.4.10.1.2 The class constructor

The class constructor does nothing. It simply invoke the Attr constructor by passing it its four arguments which are:

1. The attribute name
2. The attribute data type code
3. The attribute writable type code
4. The name of the associated write attribute

With this 4 parameters Attr class constructor, the attribute display level is not specified. Therefore it is set to its default value (OPERATOR). To set the attribute display level, it is possible to use in the constructor code the set_disp_level method. Many Attr class constructors are defined. See [8]for a complete list.

This Position attribute is a scalar attribute. For spectrum attribute, instead of inheriting from the Attr class, the class must inherits from the SpectrumAttr class. Many SpectrumAttr class constructors are defined. See [8]for a complete list.

For Image attribute, instead of inheriting from the Attr class, the class must inherits from the ImageAttr class. Many ImageAttr class constructors are defined. See [8]for a complete list.

8.4.10.1.3 The is_allowed method

This method receives two argument which are a pointer to the device object to which the attribute belongs to and the type of request (read or write). In the PositionAttr class, this method simply "forwards" the request to a method of the StepperMotor class called is_Position_allowed() passing the request type to this method. This method returns a boolean which must be set to true if the attribute is allowed. If this boolean is set to false, the DeviceImpl read_attribute method will automatically send an exception to the caller.

8.4.10.1.4 The read method

This method receives two arguments which are a pointer to the device object to which the attribute belongs to and a reference to the corresponding attribute object. This method "forwards" the request to a StepperMotor class called read_Position() passing it the reference on the attribute object.

8.4.11 The StepperMotor class

8.4.11.1 Using C++

8.4.11.1.1 The class definition file

```cpp
#include <tango.h>

#define AQSM_MAX_MOTORS 8 // maximum number of motors per device

namespace StepperMotor
{

class StepperMotor: public Tango::DeviceImpl
{
```

public:
  StepperMotor(Tango::DeviceClass *, string &);
  StepperMotor(Tango::DeviceClass *, const char *);
  StepperMotor(Tango::DeviceClass *, const char *, const char *);
  ~StepperMotor() {};

  long dev_read_position(long);
  long dev_read_direction(long);
  bool direct_cmd_allowed(const CORBA::Any &);

  virtual Tango::DevState dev_state();
  virtual Tango::ConstDevString dev_status();
  virtual void always_executed_hook();
  virtual void read_attr_hardware(vector<long> &attr_list);
  void read_Position(Tango::Attribute &);
  bool is_Position_allowed(Tango::AttrReqType req);
  void write_SetPosition(Tango::WAttribute &);
  void read_Direction(Tango::Attribute &);

  virtual void init_device();
  virtual void delete_device();
  void get_device_properties();

protected:
  long axis[AGSM_MAX_MOTORS];
  long position[AGSM_MAX_MOTORS];
  long direction[AGSM_MAX_MOTORS];
  long state[AGSM_MAX_MOTORS];

  Tango::DevLong *attr_Position_read;
  Tango::DevLong *attr_Direction_read;
  Tango::DevLong attr_SetPosition_write;
  Tango::DevLong min;
  Tango::DevLong max;
  Tango::DevLong *ptr;
};

/* End of StepperMotor namespace */

Line 1: Include the Tango master include file
Line 5: Open the StepperMotor namespace.
Line 8: The StepperMotor class inherits from the DeviceImpl class
Line 11-13: Three different object constructors
Line 14: The destructor which calls the delete_device() method
Line 16: The method to be called for the execution of the DevReadPosition command. This method must be declared as virtual if it is needed to redefine it in a class inheriting from StepperMotor. See chapter 8.7.2 for more details about inheriting.
CHAPTER 8. WRITING A TANGO DEVICE SERVER

Line 17: The method to be called for the execution of the DevReadDirection command
Line 18: The method called to check if the execution of the DevReadDirection command is allowed. This method is necessary because the DevReadDirection command is created using the template command method and the default behavior is not acceptable
Line 20: Redefinition of the dev_state. This method is used by the State command
Line 21: Redefinition of the dev_status. This method is used by the Status command
Line 23: Redefinition of the always_executed_hook method. This method is the place to code mandatory action which must be executed prior to any command.
Line 25-30: Attribute related methods
Line 32: Definition of the init_device method.
Line 33: Definition of the delete_device method
Line 35: Definition of the get_device_properties method
Line 38-50: Data members.
Line 43-44: Pointers to data for readable attributes Position and Direction
Line 45: Data for the SetPosition attribute
Line 47-48: Data members for the two device properties

8.4.11.1.2 The constructors

Three constructors are defined here. It is not mandatory to defined three constructors. But at least one is mandatory. The three constructors take a pointer to the StepperMotorClass instance as first parameter\(^6\). The second parameter is the device name as a C++ string or as a classical pointer to char array. The third parameter necessary only for the third form of constructor is the device description string passed as a classical pointer to a char array.

```
#include <tango.h>
#include <steppermotor.h>

namespace StepperMotor
{
  StepperMotor::StepperMotor(Tango::DeviceClass *cl, string &s)
  :Tango::DeviceImpl(cl,s.c_str())
  {
    init_device();
  }

  StepperMotor::StepperMotor(Tango::DeviceClass *cl, const char *s)
  :Tango::DeviceImpl(cl,s)
  {
    init_device();
  }

  StepperMotor::StepperMotor(Tango::DeviceClass *cl, const char *s, const char *d)
  :Tango::DeviceImpl(cl,s,d)
  {
    init_device();
  }

  void StepperMotor::init_device()
  {
```

\(^6\)The StepperMotorClass inherits from the DeviceClass and therefore is a DeviceClass
```cpp
27     cout << "StepperMotor::StepperMotor() create " << device_name << endl;
28
29     long i;
30
31     for (i=0; i< AGSM_MAX_MOTORS; i++)
32     {
33         axis[i] = 0;
34         position[i] = 0;
35         direction[i] = 0;
36     }
37
38     ptr = new Tango::DevLong[10];
39
40     get_device_properties();
41 }
42
43 void StepperMotor::delete_device()
44 {
45     delete [] ptr;
46 }
```

Line 1-2: Include the Tango master include file (tango.h) and the StepperMotor class definition file (steppermotor.h)

Line 4: Open the StepperMotor namespace

Line 7-11: The first form of the class constructor. It execute the Tango::DeviceImpl class constructor with the two parameters. Note that the device name passed to this constructor as a C++ string is passed to the Tango::DeviceImpl constructor as a classical C string. Then the init_device method is executed.

Line 13-17: The second form of the class constructor. It execute the Tango::DeviceImpl class constructor with its two parameters. Then the init_device method is executed.

Line 19-23: The third form of constructor. Again, it execute the Tango::DeviceImpl class constructor with its three parameters. Then the init_device method is executed.

Line 25-41: The init_device method. All the device data initialization is done in this method. The device properties are also retrieved from database with a call to the get_device_properties method at line 40. The device data member called ptr is initialized with allocated memory at line 38. It is not needed to have this pointer, it has been added only for educational purpose.

Line 43-46: The delete_device method. The rule of this method is to free memory allocated in the init_device method. In our case, only the device data member ptr is allocated in the init_device method. Therefore, its memory is freed at line 45. This method is called by the automatically added init command before it calls the init_device method. It is also called by the device destructor.

### 8.4.11.1.3 The methods used for the DevReadDirection command

The DevReadDirection command is created using the template command method. Therefore, there is no specific class needed for this command but only one object of the TemplCommandInOut class. This command needs two methods which are the dev_read_direction method and the direct_cmd_allowed method. The direct_cmd_allowed method defines here implements exactly the same behavior than the default one. This method has been used only for pedagogic issue. The dev_read_direction method will be executed by the execute method of the TemplCommandInOut class. The direct_cmd_allowed method will be executed by the is_allowed method of the TemplCommandInOut class.
long StepperMotor::dev_read_direction(long axis)
{
    if (axis < 0 || axis > AGSM_MAX_MOTORS)
    {
        WARNING_STREAM << "StepperMotor::dev_read_direction(): axis out of range" << endl;
        WARNING_STREAM << endl;
        TangoSys_OMemStream o;
        o << "Axis number " << axis << " out of range" << ends;
        throw_exception((const char *)"StepperMotor_OutOfRange",
        o.str(),
        (const char *)"StepperMotor::dev_read_direction");
    }
    return direction[axis];
}

bool StepperMotor::direct_cmd_allowed(const CORBA::Any &in_data)
{
    INFOQ_STREAM << "In direct_cmd_allowed() method" << endl;
    return true;
}

8.4.11.1.4 The methods used for the Position attribute

To enable reading of attributes, the StepperMotor class must re-define two or three methods called read_attr_hardware(), read_<Attribute_name>() and if necessary a method called is_<Attribute_name>_allowed(). The aim of the first one is to read the hardware. It will be called only once at the beginning of each read_attribute CORBA call. The second method aim is to build the exact data for the wanted attribute and to store this value into the Attribute object. Special care has been taken in order to minimize the number of data copy and allocation. The data passed to the Attribute object as attribute value is passed using pointers. It must be allocated by the method\(^1\) and the Attribute object will not free this memory. Data members called attr_<Attribute_name>_read are foreseen for this usage. The read_attr_hardware() method receives a vector of long which are indexes into the main attributes vector of the attributes to be read. The read_Position() method receives a reference to the Attribute object. The third

\(^1\)It can also be data declared as object data members or memory declared as static
method (is_Position_allowed()) aim is to allow or dis-allow, the attribute reading. In some cases, some attributes can be read only if some conditions are met. If this method returns true, the read_<Attribute_name> method will be called. Otherwise, an error will be generated for the attribute. This method receives one argument which is an enumeration describing the attribute request type (read or write). In our example, the reading of the Position attribute is allowed only if the device state is ON.

```cpp
1  void StepperMotor::read_attrHardware(vector<long> &attr_list)
2  {
3      INFO_STREAM << "In read_attrHardware for " << attr_list.size();
4      INFO_STREAM << " attribute(s)" << endl;
5      for (long i = 0; i < attr_list.size(); i++)
6          {
7              string attr_name;
8              attr_name = dev_attr->get_attr_by_ind(attr_list[i]).get_name();
9              if (attr_name == "Position")
10                 {
11                     attr_Position_read = &(position[0]);
12                 }
13              else if (attr_name == "Direction")
14                 {
15                     attr_DIRection_read = &(direction[0]);
16                 }
17          }
18  }
19
20  void read_Position(Tango::Attribute &att)
21  {
22      att.set_value(attr_Position_read);
23  }
24
25  bool is_Position_allowed(Tango::AttrReqType req)
26  {
27      if (req == Tango::WRITE_REQ)
28          return false;
29      else
30          {
31              if (get_state() == Tango::ON)
32                  return true;
33              else
34                  return false;
35          }
36  }
37```

Line 6: A loop on each attribute to be read
Line 9: Get attribute name
Line 11: Test on attribute name
Line 13: Read hardware (pretty simple in our case)
CHAPTER 8. WRITING A TANGO DEVICE SERVER 319

Line 24: Set attribute value in Attribute object using the set_value() method. This method will also initialize the attribute quality factor to Tango::ATTRVALID if no alarm level are defined and will set the attribute returned date. It is also possible to use a method called set_value_date_quality() which allows the user to set the attribute quality factor as well as the attribute date.

Line 33: Test on device state

8.4.11.1.5 The methods used for the SetPosition attribute

To enable writing of attributes, the StepperMotor class must re-define one or two methods called write_<Attribute_name>(). and if necessary a method called is_<Attribute_name>_allowed(). The aim of the first one is to write the hardware. The write_Position() method receives a reference to the WAttribute object. The value to write is in this WAttribute object. The third method (is_Position_allowed()) aim is to allow or disallow, the attribute writing. In some cases, some attributes can be write only if some conditions are met. If this method returns true, the write_<Attribute_name>() method will be called. Otherwise, an error will be generated for the attribute. This method receives one argument which is an enumeration describing the attribute request type (read or write). For read/write attribute, this method is the same for reading and writing. The input argument value makes the difference.

For our example, it is always possible to write the SetPosition attribute. Therefore, the StepperMotor class only defines a write_SetPosition() method.

```
1 void StepperMotor::write_SetPosition(Tango::WAttribute &att)
2 {
3     att.get_write_value(strr_SetPosition_write);
4     INFO_STREAM << "Attribute SetPosition value = ";
5     INFO_STREAM << attr_SetPosition_write << endl;
6     position[0] = attr_SetPosition_write;
7 }
```

Line 3: Retrieve new attribute value
Line 5-6: Send some messages using Tango Logging system
Line 8: Set the hardware (pretty simple in our case)

8.4.11.1.6 Retrieving device properties

Retrieving properties is fairly simple with the use of the database object. Each Tango device is an aggregate with a DbDevice object (see figure 8.1). This has been grouped in a method called get_device_properties(). The classes and methods of the Dbxxx objects are described in the Tango API documentation.

```
1 void DocDs::get_device_property()
2 {
3     Tango::DbData  data;
4     data.push_back(DbDatum("Max"));
5     data.push_back(DbDatum("Min"));
6     get_db_device()->get_property(data);
```
if (data[0].is_empty() == false)
    data[0] >> max;
if (data[1].is_empty() == false)
    data[1] >> min;
}

---

Line 4-5 : Two DbDatum (one per property) are stored into a DbData object
Line 7 : Call the database to retrieve properties value
Line 9-10 : If the Max property is defined in the database, extract its value from the DbDatum
object and store it in a device data member
Line 11-12 : If the Min property is defined in the database, extract its value from the DbDatum
object and store it in a device data member

8.4.11.1.7 The remaining methods

The remaining methods are the dev_state, dev_status, always_executed_hook, dev_read_position
and read_Direction() methods. The dev_state method parameters are fixed. It does not receive
any input parameter and must return a Tango.DevState data type. The dev_status parameters
are also fixed. It does not receive any input parameter and must return a Tango string. The
always_executed_hook receives nothing and return nothing. The dev_read_position method input
parameter is the motor number as a long and the returned parameter is the motor position also as
a long data type. The read_Direction() method is the method for reading the Direction attribute.

---

long StepperMotor::dev_read_position(long axis)
{
    if (axis < 0 || axis > AGSM_MAX MOTORS)
        {
            WARNING_STREAM << "StepperMotor::dev_read_position(): axis out of range!
        WARNING_STREAM << endl;
    TangoSys_OMemStream o;
    o << "Axis number " << axis " out of range" << ends;
    throw_exception((const char *)"StepperMotor_OutOfRange",
        o.str(),
        (const char *)"StepperMotor::dev_read_position");
    }
    return position[axis];
}

void always_executed_hook()
{
    INFO_STREAM << "In the always_executed_hook method << endl;
}

Tango_DevState StepperMotor::dev_state()
{
    INFO_STREAM << "In StepperMotor state command" << endl;
}
CHAPTER 8  WRITING A TANGO DEVICE SERVER

28       return DeviceImpl::dev_state();
29    }
30
31 Tango_DEVString StepperMotor::dev_status()
32 {
33   INFO_STREAM << "In StepperMotor status command" << endl;
34   return DeviceImpl::dev_status();
35 }
36
37 void read_Direction(Tango::Attribute att)
38 {
39   att.set_value(attr_Direction_read);
40 }

Line 1-18: The _dev_read_position_ method
Line 6-14: Throw exception to client if the received axis number is out of range
Line 9: A TangoSys_OMemStream is used as stream. The TangoSys_OMemStream has been defined in improve portability across platform. For Unix like operating system, it is a ostrean type. For operating system with a full implementation of the standard library, it is a ostringstream type.
Line 20-23: The _always_executed_hook_ method. It does nothing. It has been included here only as pedagogic usage.
Line 25-29: The _dev_state_ method. It does exactly what the default _dev_state_ does. It has been included here only as pedagogic usage.
Line 31-35: The _dev_status_ method. It does exactly what the default _dev_status_ does. It has been included here only as pedagogic usage.
Line 37-40: The _read_Direction_ method. Simply set the Attribute object internal value

### 8.4.11.2 Using Java

#### 8.4.11.2.1 The constructor

The constructor take a reference to the StepperMotorClass instance as first parameter^8. The second parameter is the device name as a Java string.

```java
1 package StepperMotor;
2
3 import java.util.*;
4 import org.omg.CORBA.*;
5 import fr.earf.Tango.*;
6 import fr.earf.TangoDs.*;
7
8 public class StepperMotor extends DeviceImpl implements TangoConst
9 {
10       protected final int SM_MAX_MOTORS = 8;
11
12       protected int[] axis = new int[SM_MAX_MOTORS];
13       protected int[] position = new int[SM_MAX_MOTORS];
14       protected int[] direction = new int[SM_MAX_MOTORS];
15       protected int[] state = new int[SM_MAX_MOTORS];
```

^8The StepperMotorClass inherits from the DeviceClass and therefore is a DeviceClass
protected int[] attr_Direction_read = new int[1];
protected int[] attr_Position_read = new int[1];
protected int attr_SetPosition_write;

StepperMotor(DeviceClass cl, String s, String desc,
DevState state, String status) throws DevFailed
{
    super(cl, s, desc, state, status);
    init_device();
}

public void init_device()
{
    System.out.println("StepperMotor() create motor "+ dev_name);
    int i;
    for (i = 0; i < SM_MAX_MOTORS; i++)
    {
        axis[i] = 0;
        position[i] = 0;
        direction[i] = 0;
        state[i] = 0;
    }
}

Line 3-6: Import different packages. The first one (java.lang.util) is a classical Java package from the JDK. The second one (org.omg.CORBA) is a package which contains all the CORBA related classes. The third one (fr.esrf.Tango) is the package generated by the IDL compiler from the Tango IDL file. The last one (fr.esrf.TangoDs) is the name of the package with all the root classes of the device server pattern.

Line 8 : The StepperMotor class inherits from the DeviceImpl class and implements the TangoConst interface. The TangoConst interface does not defines any method but simply defines constant variables. The TangoConst interface is a member of the TangoDs package.

Line 10 : Define an internal constant
Line 12-15 : Device internal variable
Line 17-19 : Device internal variable linked to attributes
Line 22-27 : The class constructor. It execute the DeviceImpl class constructor with five parameters. Then the init_device method is executed.

Line 29-43 : The init_device method. All the device data initialization is done in this method.

8.4.11.2.2 The methods used for the DevReadDirection command

The DevReadDirection command is created using the template command method. Therefore, there is no specific class needed for this command but only one object of the TemplateCommandInOut class. This command needs two methods which are the dev_read_direction method and the direct_cmd_allowed method. The direct_cmd_allowed method defines here implements exactly the same behavior than the default one. This method has been used only for pedagogic issue.
The dev_read_direction method will be executed by the execute method of the TemplCommandInOut class. The direct_cmd_allowed method will be executed by the is_allowed method of the TemplCommandInOut class.

```java
public int dev_read_direction(int axis) throws DevFailed {
    if (axis < 0 || axis > SM_MAX_MOTORS) {
        Util.out1.println("Steppermotor.dev_read_direction(): axis out of range");
        StringBuffer o = new StringBuffer("Axis number ");
        o.append(axis);
        o.append(" out of range");
        Exception.throw_exception("StepperMotor_AxisOutOfRange",
                                o.toString(),
                                "StepperMotor.dev_read_direction()" );
    }
    return direction[axis];
}

public boolean direct_cmd_allowed(Any data_in) {
    Util.out2.println("In StepperMotor.direct_cmd_allowed method");
    return true;
}
```

Line 1-17: The dev_read_direction method
Line 3-14: Throw exception to client if the received axis number is out of range
Line 19-24: The direct_cmd_allowed method. The command input data is passed to this method in case of it is needed to take the decision. This data is still packed into the CORBA Any object.

8.4.11.2.3 The write attribute related method

To enable writing of writable attributes, the StepperMotor class must re-define a method called write_attrHardware(). The aim of this method is to write the hardware. This method receives a vector of Integer objects as parameters. These data are the indexes of the attributes to be written into the main attribute vector stored in the MultiAttribute object. Methods of the MultiAttribute class allow the retrieval of the the correct attribute object from these indexes. The value to be written is stored in the WAttribute object and can be retrieved with WAttribute class methods called get_xx_write_value(). A data member called attr_<Attribute_name>_write is foreseen to temporary store this extracted value.

```java
public void write_attrHardware(Vector attr_list) {
    Util.out2.println("In write_attrHardware for "+attr_list.size()+" attributes");
```
for (int i = 0; i < attr_list.size(); i++)
{
    int ind = ((Integer)(attr_list.elementAt(i))).intValue();
    WAttribute att = dev_attr.get_v_attr_by_ind(ind);
    String attr_name = att.getName();
    if (attr_name.equals("SetPosition") == true)
    {
        attr_SetPosition_write = att.get_lg_write_value();
        Util.out2.println("Attribute SetPosition value = "+attr_SetPosition_write);
        position[0] = attr_SetPosition_write;
    }
}

Line 5: A loop on each attribute to be written
Line 7-9: Retrieve attribute name
Line 11: A test on attribute name
Line 13: Retrieve new attribute value
Line 15: Set the hardware (very simple in our example)

8.4.11.2.4 The read attribute related methods

To enable reading of attributes, the StepperMotor class must re-define two methods called read_attr_hardware() and read_attr(). The aim of the first one is to read the hardware. It will be called only once at the beginning of each read_attributes CORBA call. The second method aim is to build the exact data for the wanted attribute and to store this value into the Attribute object. This method will be called for each attribute to be read. Special care has been taken in order to minimize the number of data copy and allocation. The data passed to the Attribute object as attribute value is passed using pointers. It must be allocated by the method\(^8\) and the Attribute object will not free this memory. Data members called attr\_
<Attribute_name>\_read are foreseen for this usage. As for the write_attr_hardware() method, the read_attr_hardware() method receives a vector of long which are indexes into the main attributes vector of the attributes to be read. The read_attr() method receives a reference to the Attribute object.

```java
public void read_attr_hardware(Vector attr_list) {
    Util.out2.println("In read_attr_hardware for "+attr_list.size()+" attribute("
    for (int i = 0; i < attr_list.size(); i++)
    {
        int ind = ((Integer)(attr_list.elementAt(i))).intValue();
        String attr_name = dev_attr.get_attr_by_ind(ind).getName();
        if (attr_name == "Position")
        {
            attr_Position_read[0] = position[0];
        }
        else if (attr_name == "Direction")
```

\(^8\)It can also be data declared as object data members or memory declared as static
```java
14     { attr_Direction_read[0] = direction[0];
15     }
16 }
17 }
18 }
19 }
20 }
21 public void read_attr(Attribute attr) throws DevFailed
22 {
23     String attr_name = attr.get_name();
24     Util.out2.println("In read_attr for attribute "+attr_name);
25     if (attr_name.equals("Position") == true)
26     { attr.set_value(attr_Position_read);
27     }
28     else if (attr_name.equals("Direction") == true)
29     { attr.set_value(attr_Direction_read);
30     }
31 }
32 }
33 }
```

Line 4 : A loop on each attribute to be read
Line 6-7: Get attribute name
Line9 : Test on attribute name
Line11 : Read hardware (pretty simple in our case)
Line23 : Get attribute name
Line25 : Test on attribute name
Line27 : Set attribute value in Attribute object

### 8.4.11.2.5 Retrieving device properties

Retrieving properties is fairly simple with the use of the database object. Each Tango device is an aggregate with a DbDevice object (see figure 8.1). This has been grouped in a method called `get_device_properties()` . The classes and methods of the Dbxxxx objects are described in the Tango API documentation.

```java
1 void public get_device_property() throws DevFailed
2 {
3     String[] prop_names = {"Max","Min"};
4     DbDatum[] res_value = db_dev.get_property(prop_names);
5     if (res_value[0].is_empty() == false)
6         min = res_value[0].extractInt();
7     if (res_value[1].is_empty() == false)
8         max = res_value[1].extractInt();
9 }
```

Line 3 : Define the names of the properties to be retrieved
CHAPTER 8  WRITING A TANGO DEVICE SERVER

Line 5: Call the database to retrieve properties value
Line 7-8: If the Max property is defined in the database, extract its value from the DbDatum object and store it in a device data member
Line 9-10: If the Min property is defined in the database, extract its value from the DbDatum object and store it in a device data member

8.4.11.2.6 The remaining methods

The remaining methods are the dev_state, dev_status, always_executed_hook() and dev_read_position methods. The dev_state method parameters are fixed. It does not receive any input parameter and must return a DevState data type. The dev_status parameters are also fixed. It does not receive any input parameter and must return reference to a Java string. The always_executed_hook receives nothing and return nothing. The dev_read_position method input parameter is the motor number as an int and the returned parameter is the motor position also as an int data type.

```java
1  int dev_read_position(int axis) throws DevFailed
2  {
3      if (axis < 0 || axis > SM_MAX_MOTORs)
4          {
5              Util.out1.println("StepperMotor.dev_read_position(): axis out of range");
6
7              StringBuffer o = new StringBuffer("Axis number ");
8              o.append(axis);
9              o.append(" out of range");
10             }
11             throw_exception("StepperMotor.AxisOutOfRange",
12                 o.toString(),
13                 "StepperMotor.dev_read_position()");
14      }
15      return position[axis];
16  }
17
18  public void always_executed_hook()
19  {
20      Util.out2.println("In always_executed_hook method");
21  }
22
23  public DevState dev_state() throws DevFailed
24  {
25      Util.out2.println("In StepperMotor state command");
26      return super.dev_state();
27  }
28
29  public String dev_status() throws DevFailed
30  {
31      Util.out2.println("In StepperMotor status command");
32      return super.dev_status();
33  }
34
35  }
```
CHAPTER 8. WRITING A TANGO DEVICE SERVER

Line 1-18: The dev_read_position method
Line 4-15: Throw exception to client if the received axis number is out of range
Line 20-23: The always_executed_hook method. It does nothing. It has been included here only as pedagogic usage.
Line 25-29: The dev_state method. It does exactly what the default dev_state does. It has been included here only as pedagogic usage
Line 31-35: The dev_status method. It does exactly what the default dev_status does. It has been included here only as pedagogic usage.

8.5 Device server under Windows

Two kinds of programs are available under Windows. These kinds of programs are called console application or Windows application. A console application is started from a MS-DOS window and is very similar to classical UNIX program. A Windows application is most of the time not started from a MS-DOS window and is generally a graphical application without standard input/output. Writing a device server in a console application is straightforward following the rules described in the previous sub-chapters. Writing a device server in a Windows application needs some changes detailed in the following sub-chapters.

8.5.1 The Tango device server graphical interface

Within the Windows operating system, most of the running application has a window user interface. This is also true for the Windows Tango device server. Using or not this interface is up to the device server programmer. The choice is done with an argument to the server_init() method of the Tango::Util class. This interface is pretty simple and is based on three windows which are:

- The device server main window
- The device server console window
- The device server help window

8.5.1.1 The device server main window

This window looks like:
Four menus are available in this window. The File menu allows the user to exit the device server. The View menu allows you to display/hide the device server console window. The Debug menu allows the user to change the server output verbose level. All the outputs goes to the console window even if it is hidden. The Help menu displays the help window. The device server name is displayed in the window title. The text displayed at the bottom of the window has a default value (the one displayed in this window dump) but may be changed by the device server programmer using the set_main_window_text() method of the Tango::Util class. If used, this method must be called prior to the call of the server_init() method. Refer to [8] for a complete description of this method.

8.5.1.2 The console window

This window looks like:

```
opal/andy - Console
1 device(s) defined
Device name: et/opcl
Entering MultiAttribute class constructor for device et/opcl
Leaving MultiAttribute class constructor
Fluids::Fluids() create device et/opcl
DeviceClass::export_device() arrived
Leaving DeviceClass::export_device method()
DeviceClass::export_device() arrived
Leaving DeviceClass::export_device method()
```
8.5.1.3 The help window

This window looks like:

![Help window](image)

This window displays:

- The device server name
- The Tango library release
- The Tango IDL definition release
- The device server release. The device server programmer may set this release number using the `set_server_version()` method of the Tango::Util class. If used, this must be done prior to the call of the `server_init()` method. If the `set_server_version()` method is not used, `xy` is displays as version number. Refer to [8] for a complete description of this method.

8.5.2 MFC device server

There is no `main` function within a classical MFC program. Most of the time, your application is represented by one instance of a C++ class which inherits from the MFC CWinApp class. This CWinApp class has several methods that you may overload in your application class. For a device server to run correctly, you must overload two methods of the CWinApp class. These methods are the `GetInstance()` and `ExitInstance()` methods. The rule of these methods is obvious following their names.

Remember that if the Tango device server graphical user interface is used, you must link your device server with the Tango windows resource file. This is done by adding the Tango resource file to the Project Settings/Link/Input/Object, library modules window in VC++.

8.5.2.1 The `GetInstance` method

The code to be added here is the equivalent of the code written in a classical `main()` function. Don’t forget to add the `tango.h` file in the list of included files.
1     BQQL FluidsApp::InitInstance()
2     {
3         AfxEnableControlContainer();
4         // Standard initialization
5         // If you are not using these features and wish to reduce the size
6         // of your final executable, you should remove from the following
7         // the specific initialization routines you do not need.
8         #ifdef _AFXDLL
9             Enable3dControls(); // Call this when using MFC in a shared DLL
10         #else
11             Enable3dControlsStatic(); // Call this when linking to MFC statically
12         #endif
13         Tango::Util *tg;
14         try
15         {
16             tg = Tango::Util::init(m_hInstance, m_nCmdShow);
17             tg->server_init(true);
18             tg->server_run();
19         }
20         catch (bad_alloc)
21         {
22             MessageBox((HWND)NULL, "Memory error", "Command line", MB_ICONSTOP);
23             return(FALSE);
24         }
25         catch (Tango::DevFailed &e)
26         {
27             MessageBox((HWND)NULL,e.errors[0].desc.in(),"Command line",MB_ICONSTOP);
28             return(FALSE);
29         }
30         catch (CORBA::Exception &)
31         {
32             MessageBox((HWND)NULL,"Exception CORBA","Command line",MB_ICONSTOP);
33             return(FALSE);
34         }
35         m_pMainWnd = new CWnd;
36         m_pMainWnd->Attach(tg->get_ds_main_window());
37         return TRUE;
38     }

Line 19: Initialise Tango system. This method also analyses the argument used in command line.
Line 21: Create Tango classes requesting the Tango Windows graphical interface to be used
Line 23: Start Network listener. Note that under NT, this call returns in the contrary of UNIX like operating system.
CHAPTER 8  WRITING A TANGO DEVICE SERVER

Line 26-30: Display a message box in case of memory allocation error and leave method with a return value set to false in order to stop the process.

Line 31-35: Display a message box in case of error during server initialization phase.

Line 36-40: Display a message box in case of error other than memory allocation. Leave method with a return value set to false in order to stop the process.

Line 37-38: Create a MFC main window and attach the Tango graphical interface main window to this MFC window.

8.5.2.2 The ExitInstance method

This method is called when the application is stopped. For Tango device server, its rule is to destroy the Tango::Util singleton if this one has been correctly constructed.

```c++
1  int FluidsApp::ExitInstance() 
2  { 
3      bool del = true; 
4    
5      try 
6      { 
7         Tango::Util *tg = Tango::Util::instance(); 
8       } 
9      catch(Tango::DevFailed) 
10     { 
11         del = false; 
12     } 
13     if (del == true) 
14         delete (Tango::Util::instance()); 
15     } 
16     return CWinApp::ExitInstance(); 
17  }
```

Line 7: Try to retrieve the Tango::Util singleton. If this one has not been constructed correctly, this call will throw an exception.

Line 9-12: Catch the exception in case of incomplete Tango::Util singleton construction

Line 14-15: Delete the Tango::Util singleton. This will unregister the Tango device server from the Tango database.

Line 17: Execute the ExitInstance method of the CWinApp class.

If you don’t want to use the Tango device server graphical interface, do not pass any parameter to the server_init() method and instead of the code display in lines 37 and 38 in the previous example of the InitInstance() method, use your own code to initialize your own application.

8.5.2.3 Example of how to build a Windows device server MFC based

This sub-chapter gives an example of what it is needed to do to build a MFC Windows device server. Rather than being a list of actions to strictly follow, this is some general rules of how using VC++ to build a Tango device server using MFC.

1. Create your device server using Pogo. For a class named MyMotor, the following files will be needed: class factory.cpp, MyMotorClass.h, MyMotorClass.cpp, MyMotor.h and MyMotor.cpp.
2. On a Windows computer running VC++, create a new project of type “MFC app Wizard (exe)” using static MFC libs. Ask for a dialog based project without ActiveX controls.

3. Copy the five files generated by Pogo to the Windows computer and add them to your project.

4. Remove the dialog window files (xxxDlg.cpp and xxxDlg.h), the Resource include file and the resource script file from your project.

5. Add #include <stdafx.h> as first line of the include files list in class_factory.cpp, MyMotorClass.cpp and MyMotor.cpp file. Also add your own directory and the Tango include directory to the project pre-compiler include directories list.

6. Enable RTTI in your project settings (see chapter 8.6.1.2)

7. Change your application class:

   (a) Add the definition of an ExitInstance method in the declaration file. (xxx.h file)
   (b) Remove the include of the dialog window file in the xxx.cpp file and add an include of the Tango master include files (tango.h)
   (c) Replace the InitInstance() method as described in previous sub-chapter. (xx.cpp file)
   (d) Add an ExitInstance() method as described in previous sub-chapter (xxx.cpp file)

8. Add all the libraries needed to compile a Tango device server (see chapter 8.6.1.2) and the Tango resource file to the linker Object Libraries modules.

### 8.5.3 Win32 application

Even if it is more natural to use the C++ structure of the MFC class to write a Tango device server, it is possible to write a device server as a Win32 application. Instead of having a main() function as the application entry point, the operating system, provides a WinMain() function as the application entry point. Some code must be added to this WinMain function in order to support Tango device server. Don’t forget to add the tango.h file in the list of included files.

```cpp
1  int APIENTRY WinMain(HINSTANCE hInstance,
2           HINSTANCE hPrevInstance,
3           LPSTR    lpCmdLine,
4           int      nCmdShow)
5  {
6         MSG msg;
7         Tango::Util *tg;
8
9         try
10        {
11             tg = Tango::Util::init(hInstance,nCmdShow);
12
13             string txt;
14             txt = "Blaba first line\n";
15             txt = txt + "Blaba second line\n";
16             txt = txt + "Blaba third line\n";
17             tg->set_main_window_text(txt);
18             tg->set_server_version("2.2");
19
20             tg->server_init(true);
```
CHAPTER 8  WRITING A TANGO DEVICE SERVER

21
tg->server_run();
22
23
24 }
25 catch (bad_alloc)
26 {
27 MessageBox((HWND)NULL,"Memory error","Command line",MB_ICONSTOP);
28 return (FALSE);
29 }
30 catch (Tango::DevFailed &e)
31 {
32 MessageBox((HWND)NULL,e.errors[0].desc.in(),"Command line",MB_ICONSTOP);
33 return (FALSE);
34 }
35 catch (CORBA::Exception &)
36 {
37 MessageBox((HWND)NULL,"Exception CORBA","Command line",MB_ICONSTOP);
38 return (FALSE);
39 }
40
41 while (GetMessage(&msg, NULL, 0, 0))
42 {
43 TranslateMessage(&msg);
44 DispatchMessage(&msg);
45 }
46 delete tg;
47 return msg.wParam;
48 }

Line 11 : Create the Tango::Util singleton
Line 13-18 : Set parameters for the graphical interface
Line 20 : Initialize Tango device server requesting the display of the graphical interface
Line 22 : Run the device server
Line 25-39 : Display a message box for all the kinds of error during Tango device server initialization phase and exit WinMain function.
Line 41-45 : The Windows message loop
Line 47 : Delete the Tango::Util singleton. This class destructor unregisters the device server from the Tango database.

Remember that if the Tango device server graphical user interface is used, you must link your device server with the Tango windows resource file. This is done by adding the Tango resource file to the Project Settings/Link/Input/Object,library modules window in VC++.

If you don’t want to use the tango device server graphical user interface, do not use any parameter in the call of the server_init() method and do not link your device server with the Tango Windows resource file.

8.5.4 Device server as NT service

With Windows NT, if you want to have processes which survive to logoff sequence and/or are automatically started during computer startup sequence, you have to write them as service. It is possible to write Tango device server as service. You need to
1. Write a class which inherits from a pre-written Tango class called NTService. This class must have a *start* method.

2. Write a main function following a predefined skeleton.

### 8.5.4.1 The Service class

It must inherits from the *NTService* class and defines a *start* method. The NTService class must be constructed with one argument which is the device server executable name. The *start* method has three arguments which are the number of arguments passed to the method, the argument list and a reference to an object used to log info in the NT event system. The first two args must be passed to the Tango::Util::init method and the last one is used to log error or info messages. The class definition file looks like

```cpp
1 #include <tango.h>
2 #include <ntservice.h>
3
4 class MYService: public Tango::NTService
5 {
6     public:
7         MYService(char *);
8     void start(int argc, char **, Tango::NTEventLogger *);
9 }
```

*Line 1-2: Some include files*

*Line 4: The MYService class inherits from Tango::NTService class*

*Line 7: Constructor with one parameter*

*Line 9: The *start()* method*

The class source code looks like

```cpp
1 #include <myservice.h>
2 #include <tango.h>
3
4 using namespace std;
5
6 MYService::MYService(char *exec_name):NTService(exec_name)
7 {
8 }
9
10 void MYService::start(int argc, char **argv,Tango::NTEventLogger *logger)
11 {
12     Tango::Util *tg;
13     try
14     {
15         Tango::Util::_service = true;
16         tg = Tango::Util::init(argc,argv);
17     }
18 ```
CHAPTER 8  WRITING A TANGO DEVICE SERVER  335

19    tg->server_init();
20    tg->server_run();
21    }
22    catch (bad_alloc)
23    {
24        logger->error("Can’t allocate memory to store device object");
25    }
26    catch (Tango::DevFailed &e)
27    {
28        logger->error(e.errors[0].desc.in());
29    }
30    catch (CORBA::Exception &)
31    {
32        logger->error("CORBA Exception");
33    }
34  }

Line 6-8: The MYSservice class constructor code.
Line 15: Set to true the _service static variable of the Tango::Util class.
Line 17-21: Classical Tango device server startup code
Line 23-34: Exception management. Please, note that within a service, it is not possible to
print data on a console. This method receives a reference to a logger object. This object sends all
its output to the Windows NT event system. It is used to send messages when an exception has
occurred.

8.5.4.2 The main function
The main function is used to create one instance of the class describing the service, to check the
service option and to run the service. The code looks like:

1  #include <tango.h>
2  #include <MYSservice.h>
3  using namespace std;
4  int main(int argc,char *argv[])
5  {
6      MYSservice service(argc[(argv[]));
7      int ret;
8      if ((ret = service.options(argc,argv)) <= 0)
9          return ret;
10     service.run(argc,argv);
11     return 0;
CHAPTER 8. WRITING A TANGO DEVICE SERVER

Line 9: Create one instance of the MYService class with the executable name as parameter
Line 12: Check service option with the options() method inherited from the NTService class.
Line 15: Run the service. The run() method is inherited from the NTService class. This method will after some NT initialization sequence execute the user start() method.

8.5.4.3 Service options and messages

When a Tango device server is written as a Windows NT service, it supports several new options. These option are linked to Windows NT service usage.

Before it can be used, a service must be installed. A name and a title is associated to each service. For Tango device server used as service, the service name is build from the executable name followed by the underscore character and the instance name. For example, a device server service executable file named "opc" and started with "fluids" as instance name, will be named "opc_fluids".
The title string is built from the service executable name followed by the sentence "Tango device server" and the instance name between parenthesis. In the previous example, the service title will be "opc Tango device server (fluids)". Once a service is installed, you can configure it with the "Services" application of the control panel. Services title are displayed by this application and allow the user to select one specific service. Once a service is selected, it is possible to start/stop it and to configure its startup type as manual (with the Services application) or as automatic. When the automatic mode is chosen, the service starts when the computer is started. In this case, the service executable code must resides on the computer local disk.

Tango device server logs message in the Windows event system when the service is started or stopped. You can see these messages with the "Event Viewer" application (Start->Programs->Administrative tools->Event Viewer) and choose the Application events.

The new options are -i, -s, -u, -h and -d.

- -i : Install the service
- -s : Install the service and choose the automatic startup mode
- -u : Un-install the service
- -dbg : Run in console mode to debug service. The service must have been installed prior to used it. The classical -v device server option can be used with the -d option.

On the command line, all these options must be used after the device server instance name ("opc fluids -i" to install the service, "opc fluids -u" to un-install the service, "opc fluids -v -d" to debug the service)

8.5.4.4 Tango device server using MFC as Windows NT service

If your Tango device server uses MFC and must be written as a Windows NT service, follow these rules:

- Don't forget to add the stdafx.h file as the first file included in all the source files making the project.
- Comment out the definition of VC_EXTRALEAN in the stdafx.h file.
- Change the preprocessor definitions, replace _WINDOWS by _CONSOLE
- Add the /SUBSYSTEM:CONSOLE option in the linker options window of the project settings.
- Add a call to initialize the MFC (AfxWinInit()) in the service main function
8.6 Compiling, linking and executing a TANGO device server process

8.6.1 Compiling and linking a C++ device server

8.6.1.1 On UNIX like operating system

8.6.1.1.1 Supported development tools

The supported compiler for Linux is gcc release 2.95.3 and above. For Solaris with its native C++ compiler, CC release 5.3 is supported (FORTE C++ 6 Update 2). Please, note that to debug a Tango device server running under Linux, gdb release 5 and above is needed in order to correctly handle threads.

8.6.1.1.2 Compiling

TANGO for C++ uses omniORB (release 4) as underlying CORBA Object Request Broker [11]. To compile a TANGO device server, your include search path must be set to :

- The omniORB include directory
- The Tango include directory
- Your development directory

8.6.1.1.3 Linking

To build a running device server process, you need to link your code with several libraries. Nine of them are always the same whatever the operating system used is. These nine libraries are:

- The Tango libraries (called libtango and liblog4tango)
- Three omniORB package libraries (called libomniORB4, libomniDynamic4 and lib-
cos4)
• The omniORB threading library (called libomnithread)

On top of that, you need additional libraries depending on the operating system:

• For Solaris 7, add the posix4 library (libposix4), the socket library (libsocket), the nsl library (libnsl) and the posix thread library (libpthread)

• For Linux (Suse 7), add the posix thread library (libpthread)

The following table summarizes the necessary options to compile a Tango C++ device server. Obviously, the options -I and -L must be updated to reflect your file system organization.

<table>
<thead>
<tr>
<th>Operating system</th>
<th>Compiling option</th>
<th>Linking option</th>
</tr>
</thead>
<tbody>
<tr>
<td>Solaris CC</td>
<td>-mt -I.</td>
<td>-mt -L -ltango -llog4tango -lomniorb4 -loomnity Dynamic4 -1cos4 -lomnithread -lposix4 -lsocket -linsl -lpthread</td>
</tr>
<tr>
<td>Linux gcc</td>
<td>-D_REENTRANT -I.</td>
<td>-L. -ltango -llog4tango -lomniorb4 -loomnity Dynamic4 -1cos4 -lomnithread -lpthread</td>
</tr>
</tbody>
</table>

The following is an example of a Makefile for Linux. Obviously, all the paths are set to the ESRF file system structure.

```makefile
1 #
2 # Makefile to generate a Tango server
3 #
4 CC = c++
5 BIN_DIR = suse82
6 TANGO_HOME = /segfs/tango
7 INCLUDE_DIRS = -I $(TANGO_HOME)/include/$(BIN_DIR) \
8 -I .
9
10 LIB_DIRS = -L $(TANGO_HOME)/lib/$(BIN_DIR)
11
12 CXXFLAGS = -D_REENTRANT $(INCLUDE_DIRS)
13 LFLAGS = $(LIB_DIRS) -ltango \
14 -llog4tango \n15 -lomniorb4 \n16 -loomnity Dynamic4 \n17 -1cos4 \n18 -lomnithread \n19 -lpthread
20
21 SVC_OBJC = main.o \
22 classfactory.o \
23
24
25
26```
27         stepperomotorclass.o \\
28         stepperomotor.o
29
30
31 .SUFFIXES: .o .cpp
32 .cpp.o:
33         $(CC) $(CXXFLAGS) -c <
34
35
36 all: StepperMotor
37
38 StepperMotor: $(SVC_OBJC)
39         $(CC) $(SVC_OBJC) -o $(BIN_DIR)/StepperMotor $(LFLAGS)
40
41 clean:
42         rm -f *.o core

Line 5-7 : Define Makefile macros
Line 9-10 : Set the include file search path
Line 12 : Set the linker library search path
Line 15 : The compiler option setting
Line 16-22 : The linker option setting
Line 25-28 : All the object files needed to build the executable
Line 31-33 : Define rules to generate object files
Line 36 : Define a "all" dependency
Line 38-39 : How to generate the StepperMotor device server executable
Line 41-42 : Define a "clean" dependency

8.6.1.2 On Windows NT using Developer Studio

Supported Windows compiler for Tango is Visual C++ release 6 with its service pack number 3 installed. Most problems in building a Windows device server relate around the /M compiler switch family. This switch family controls which run-time library names are embedded in the object files, and consequently which libraries are used during linking. Attempt to mix and match compiler settings and libraries can cause link error and even if successful, may produce undefined run-time behavior.

Selecting the correct /M switch in Developer Studio is done through a dialog box. To open this dialog box, click on the "Project" menu and select the "Settings" option. To change the compiler switch click on the "C/C++" tab and select "Code Generation" from the "Category" drop-down list. The "Use run-time library" drop-down list is used to change the compiler switch. By looking at the string in the "Project options" edit box, you can see what the switch value is for the drop-down list selection.

- Single-threaded = /ML
- Multithreaded = /MT (Supported)
- Multithreaded DLL = /MD (Supported)
- Debug Single-threaded = /MLd
- Debug Multithreaded = /MTd (Supported)
- Debug Multithreaded DLL = /MDd (Supported)
Compiling a file with a value of the /M switch family will impose at link phase the use of libraries also compiled with the same value of the /M switch family. If you compiled your source code with the /MT option (Multithreaded), you must link it with libraries also compiled with the /MT option.

The omniORB package used by TANGO, makes extensive use of exceptions and RTTI\(^\text{10}\). This requires the /GX and /GR options be enabled when compiling. The setting can be found in Developer Studio in the “Project Settings” dialog box. Click on the “C/C++” tab and select “C++ language” in the “Category” drop-down list.

omniORB and TANGO relies on the preprocessor identifier WIN32 being defined in order to configure itself. Normally this will already be defined in a Developer Studio created project. If you build an application using static libraries (option /MT or /MTd), you must add _WINSTATIC to the list of the preprocessor identifiers. If you build an application using DLL (option /MD or /MDd), you must add LOG4TANGO_HAS_DLL and TANGO_HAS_DLL to the list of preprocessor identifiers.

To build a running device server process, you need to link your code with several libraries on top of the Windows libraries. These libraries are:

- The Tango libraries (called tango.lib and log4tango.lib or tango.lib and log4tangod.lib for debug mode)
- The omniORB package libraries (see next table)

<table>
<thead>
<tr>
<th>Compile mode</th>
<th>Libraries</th>
</tr>
</thead>
<tbody>
<tr>
<td>Debug Multithreaded</td>
<td>omniORB4d.lib, omniDynamic4d.lib, omnithreadd.lib and COS4d.lib</td>
</tr>
<tr>
<td>Multithreaded</td>
<td>omniORB4.lib, omniDynamic4.lib, omnithread.lib and COS.lib</td>
</tr>
<tr>
<td>Debug Multithreaded DLL</td>
<td>omniORB405_rtd.lib, omniDynamic405_rtd.lib, omnithread30_rtd.lib, and COS405_rtd.lib</td>
</tr>
<tr>
<td>Multithreaded DLL</td>
<td>omniORB405_rt.lib, omniDynamic405_rt.lib, omnithread30_rt.lib, and COS405_rt.lib</td>
</tr>
</tbody>
</table>

- Windows network libraries (mswssock.lib and ws2_32.lib)
- Windows graphic library (comet132.lib)

To add these libraries in Developer Studio, open the “Project Settings” dialog box and click on the “Link” tab. Select “Input” from the “Category” drop-down list and add these library names to the list of library in the “Object/library modules” box.

The “Win32 Debug” or “Win32 Release” configuration that you choose with the “Build/Set active configuration” menu changes the /M switch compiler. For instance, if you select a “Win32 Debug” configuration in a “non-DLL” project, use the omniORB4d.lib, omniDynamic4d.lib and omnithreadd.lib libraries and the tango.lib library in the debug directory (at the ESRF). If you select the “Win32 Release” configuration, use the omniORB4.lib, omniDynamic4.lib and omnithread.lib libraries and the tango.lib library in the release directory (at the ESRF).

**WARNING:** In some cases, the Microsoft Visual Studio wizard used during project creation generates an include file called Stdafx.h. If this file itself includes windows.h file, you have to add the preprocessor macro _WIN32_WINNT and set it to 0x0400.

### 8.6.2 Running a C++ device server

To run a C++ Tango device server, you must set an environment variable. This environment variable is called **TANGO_HOST** and has a fixed syntax which is

\(^{10}\)RTTI stands for Run Time Type Identification
CHAPTER 8. WRITING A TANGO DEVICE SERVER

TANGO_HOST=<host>:<port>

The host field is the host name where the TANGO database device server is running. The port field is the port number on which this server is listening. For instance, a valid syntax is TANGO_HOST=dumela:10000. For UNIX like operating system, setting environment variable is possible with the export or setenv command depending on the shell used. For Windows NT, setting environment variable is possible with the “Environment” tab of the “System” application in the control panel.

If you need to start a Tango device server on a pre-defined port (For Tango database device server or device server without database usage), you must use one of the underlying ORB option endpoint like

myserver myinstance_name -ORBendPoint giop:tcp::<port number>

8.6.3 Compiling a Java device server

8.6.3.1 Supported java release

Tango device server written using Java language needs release 1.4.0 (or above) of the Java environment.

8.6.3.2 Setting the CLASSPATH

To correctly compile a Java Tango device server, the CLASSPATH environment variable must be set to:

- The Tango jar file, All Tango and TangoDs package classes have been stored in this jar file. On top of that, this file also includes all the CORBA ORB classes (JavORB classes). This file is named TangORB.jar
- The jar file with all the JDK classes (not always necessary, could be implicit)
- Your own directory

For UNIX like operating system, setting environment variable is done with the export or setenv command depending on the shell used. For Windows NT, setting environment variable is possible with the “Environment” tab of the “System” application in the control panel.

8.6.3.3 Makefile

The following is an example of a Makefile for a Java Tango device server. Obviously, all the paths are set to the ESRF file system structure.

```
1 #
2 # Makefile to generate a TANGO java device server
3 #
4
5 JAVAC = javac -classpath $(CLASSPATH):
6
7 # -------------------------------------------------------------
8 #
9 # The compiler flags
10 #
11 #-------------------------------------------------------------
12```
CHAPTER 8. WRITING A TANGO DEVICE SERVER

```
13  JAVAFLAGS = -g
14
15  #---------------------------------------------------------------------
16
17  CL_LIST =   DevReadPositionCmd.class  \
18         StepperMotor.class \n19         StepperMotorClass.class
20
21  PACKAGE = server
22
23  #
24  # Rule for compiling
25  #
26 27  .SUFFIXES: .class .java
28  .java.class:
29      $(JAVAC) $(JAVAFLAGS) $<
30
31  #---------------------------------------------------------------------
32
33
34  all: $(PACKAGE)
35
36  $(PACKAGE):  $(CL_LIST)
37
38  clean:
39      rm -f *.class
```

Line 5: Definition of the java compiler
Line 13: The java compiler flag
Line 18: List of class to be compiled
Line 28: Define a dependency name
Line 29-30: Define how source files must be compiled
Line 35: The “all” dependency
Line 47: The device server dependency
Line 39-40: The “clean” dependency

8.6.3.4 Tango core software release number

All the Tango core classes are packaged in the Tango.jar file. A little utility tool called TangoVers allows a user to know which release of the Tango core classes he(she) is using. This utility is available only with Java 1.2 virtual machine. To run this utility, simply type

```
TangoVers <path to Tango.jar file>
```

if the directory /segfs/tango/bin is in your PATH environment variable.

8.6.4 Running a Java device server

A correct setting of the CLASSPATH environment variable is not enough to run a Java Tango device server. You must also set a Java system property. The name of the system property is TANGO_HOST and its syntax is the same than the syntax described in chapter 8.6.2. Setting
CHAPTER 8. WRITING A TANGO DEVICE SERVER

a Java system property is done by using -D option of the java interpreter command. To run a Java Tango device server, the command line must start with

```
java -DTANGO_HOST=<host>:<port> xxxx
```

As all the device server files are part of a package, you have to run this command in the directory above the package directory. For instance, for our StepperMotor device server started with et as instance name, all files must be stored in a directory called StepperMotor and the command line must be

```
java -DTANGO_HOST=<host>:<port> StepperMotor/StepperMotor et
```

run from the directory above the StepperMotor one.

If you need to start a Tango device server on a pre-defined port (for Tango database device server or device server without database usage), you must use one of the underlying ORB option OAPort like

```
java -DOAPort=<port number> myserver myinstance_name
```

8.7 Advanced programming techniques

The basic techniques for implementing device server pattern are required by each device server programmer. In certain situations, it is however necessary to do things out of the ordinary. This chapter will look into programming techniques which permit the device server serve more than simply the network.

8.7.1 Receiving signal (C++ specific)

It is **UNSAFE** to use any CORBA call in a signal handler. It is also UNSAFE to use some system calls in a signal handler. Tango device server solved this problem by using threads. A specific thread is started to handle signals. Therefore, every Tango device server is automatically a threaded process. This allows the programmer to write the code which must be executed when a signal is received as ordinary code. All device server threads mask all signals except the specific signal thread which is permanently waiting for signal. If a signal is sent to a device server process, only the signal thread will receive it because it is the single thread which does not mask signals.

Nevertheless, signal management is not trivial and some care have to be taken. The signal management differs from operating system to operating system. It is not recommended that you install your own signal routine using any of the signal routines provided by the operating system calls or library.

8.7.1.0.1 Using Linux

The classical thread library is used by the Tango device server. The thread management offered by the Linux kernel and this library is a pure kernel-thread based implementation. This means that each thread is seen as a process (each thread has a separate PID, the ps command displays one line for each thread) even if they are not real process. For a Tango device server, a ps command will show you several threads. One of them is the signal thread (the fifth one). Chapter 9.3 details how thread are managed within a Tango device server or client.

The PID stored in the Tango database is the PID of the signal thread. All signals should be sent to the signal thread. To kill a server from a console window, the PID of the signal thread should be used. The Linux thread library is using the SIGUSR1 and SIGUSR2 signal for its own purpose. It is forbidden to use these two signals in a Linux Tango device server. The Tango core classes will refuse to install something for these two signals.

Nevertheless, the Linux thread library is not fully POSIX compliant about thread and signal management. The POSIX specification says that an asynchronous signal must be delivered to one
of the thread of the program which does not block the signal (it is not specified which). Using
this Linux thread library, the signal is delivered to the thread it is been sent to, based on the PID
of the thread. If that thread is currently blocking the signal, the signal remains pending...This is
a problem for Tango device server under Linux using the alarm() system call. In this case, the
system will send the signal to the device server thread which has called alarm() and not to the
device server signal management thread. A special case of the register_signal method (detailed
in the next sub-chapter) have been developed for such case. This is available only for Linux.

8.7.1.0.2 Using Solaris
There is no restriction on the signal to be used.

8.7.1.1 Using signal
It is possible for C++ device server to receive signals from drivers or other processes. The TDSOM
supports receiving signal at two levels: the device level and the class level. Supporting signal at
the device level means that it is possible to specify interest into receiving signal on a device basis.
This feature is supported via three methods defined in the DeviceImpl class. These methods are
called register_signal, unregister_signal and signal_handler.

The register_signal method has one parameter which is the signal number. This method
informs the device server signal system that the device want to be informed when the signal
passed as parameter is received by the process. There is a special case for Linux as explained in
the previous sub-chapter. It is possible to register a signal to be executed in the a signal handler
context (with all its restrictions). This is done with a second parameter to this register_signal
method. This second parameter is simply a boolean data. If it is true, the signal_handler will be
executed in a signal handler context in the device server main thread. A default value (false) has
been defined for this parameter.

The unregister_signal method also have an input parameter which is the signal number.
This method removes the device from the list of object which should be warned when the signal
is received by the process.

The signal_handler method is the method which is triggered when a signal is received if the
previously registered signal has been executed. This method is defined as virtual and can be
redefined by the user. It has one input argument which is the signal number.

The same three methods also exist in the DeviceClass class. Their action and their usage are
similar to the DeviceImpl class methods. Installing a signal at the class level does not mean that all
the device belonging to this class will receive the signal. This only means that the signal_handler
method of the DeviceClass instance will be executed. This is useful if an action has to be executed
once for a class of devices when a signal is received.

The following code is an example with our stepper motor device server configured via the
database to serve three motors. These motors have the following names: id04/motor/01, id04/motor/02
and id04/motor/03. The signal SIGALRM (alarm signal) must be propagated only to the motor
number 2 (id04/motor/02)

```c++
1  void StepperMotor::init_device()
2  {
3      cout << "StepperMotor::StepperMotor() create motor " << dev_name << endl;
4  
5      long i;
6  
7      for (i=0; i< AGSM_MAX_MOTORS; i++)
8      {
9          axis[i] = 0;
10          position[i] = 0;
```

```c++
```
The `init_device` method is modified.

Line 14-15: The device name is checked and if it is the correct name, the device is registered in the list of devices wanted to receive the SIGALRM signal.

The destructor is also modified.

Line 20: Unregister the device from the list of devices which should receive the SIGALRM signal. Note that unregister a signal for a device which has not previously registered its interest for this signal does nothing.

The `signal_handler` method is redefined.

Line 25: Print signal number

Line 27: Do what you have to do when the signal SIGALRM is received.

If all devices must be warned when the device server process receives the signal SIGALRM, removes line 14 in the `init_device` method.

### 8.7.1.2 Exiting a device server gracefully

A device server has to exit gracefully by unregistering itself from the database. The necessary action to gracefully exit are automatically executed on reception of the following signal:

- SIGINT, SIGTERM, SIGHUP and SIGQUIT for device server running on Solaris or Linux
- SIGINT, SIGTERM, SIGABRT and SIGBREAK for device server running on Windows-NT

This does not prevent the device server to also register interest at device or class levels for those signals. The user installed `signal_handler` method will first be called before the graceful exit.

### 8.7.2 Inheriting

This sub-chapter describes how it is possible to inherit from an existing device pattern implementation. As the device pattern includes more than a single class, inheriting from an existing device pattern needs some explanations.

Let us suppose that the existing device pattern implementation is for devices of class A. This means that classes A and AClass already exists plus classes for all commands offered by device of class A. One new device pattern implementation for device of class B must be written with all the features offered by class A plus some new one. This is easily done with the inheritance. Writing a device pattern implementation for device of class B which inherits from device of class A means:
CHAPTER 8  WRITING A TANGO DEVICE SERVER

- Write the BClass class
- Write the B class
- Write B class specific commands
- Eventually redefine A class commands

8.7.2.1 Using C++

The miscellaneous code fragments given below detail only what has to be updated to support device pattern inheritance

8.7.2.1.1 Writing the BClass

As you can guess, BClass has to inherit from AClass. The command_factory method must also be adapted.

```cpp
namespace B
{

class BClass : public A::AClass
{
   .
   ....
}

BClass::command_factory()
{
   A::AClass::command_factory();
   command_list.push_back(...);
}

} /* End of B namespace */
```

Line 1: Open the B namespace
Line 4: BClass inherits from AClass which is defined in the A namespace.
Line 11: Only the command_factory method of the BClass will be called at start-up. To create the AClass commands, the command_factory method of the AClass must also be executed. This is the reason of the line
Line 13: Create BClass commands

8.7.2.1.2 Writing the B class

As you can guess, B has to inherits from A.

```cpp
namespace B
{

class B : public A::A
{

```
6       ..... 
7   
8   B::B(Tango::DeviceClass *cl, const char *s):A::A(cl,s) 
9   { 
10      .... 
11      init_device(); 
12   } 
13   
14   void B::init_device() 
15   { 
16      .... 
17   } 
18   
19   } /* End of B namespace */

Line 1 : Open the B namespace.
Line 4 : B inherits from A which is defined in the A namespace
Line 9 : The B constructor calls the right A constructor

8.7.2.13 Writing B class specific command

Noting special here. Write these classes as usual

8.7.2.14 Redefining A class command

It is possible to redefine a command which already exist in class A only if the command is created using the inheritance model (but keeping its input and output argument types). The method which really execute the class A command is a method implemented in the A class. This method must be defined as virtual. In class B, you can redefine the method executing the command and implement it following the needs of the B class.

8.7.2.2 Using Java

The miscellaneous code fragments given below detail only what has to be updated to support device pattern inheritance

8.7.2.2.1 Writing the BClass

As you can guess, BClass has to inherit from AClass. Some change must be done in the definition of the init and instance methods. The command_factory method must also be adapted.

1   public class BClass extends AClass implements TangoConst 
2   { 
3      public static AClass init(String name) throws DevFailed 
4      { 
5      } 
6      
7      public static AClass instance() 
8      { 
9      } 
10     

CHAPTER 8. WRITING A TANGO DEVICE SERVER

11 }
12 public void command_factory()
13 {
14     super.command_factory();
15     command_list.addElement(...);
16 }
17 
18 
19 

Line 1: BClass inherits from AClass and implements TangoConst interface

Line 3: The return data type of the init method must be the same as the type defines in the
AClass (therefore a reference to AClass) otherwise, the compiler complains. BClass inherits from
AClass and a reference to a BClass is also a reference to the AClass

Line 8: The return data type of the instance method must also be adapted as explained for
the init method

Line 15: Only the command_factory method of the BClass will be called at start-up. To
create the AClass commands, the command_factory method of the AClass must also be executed.
This is the reason of the line

Line 17: Create BClass commands

8.7.2.2.2 Writing the B class

As you can guess, B has to inherits from A. The init_device method must be adapted, the
constructor has to be modified and an instance variable must be added

1  public class B extends A implements TangoConst
2  {
3      boolean constructed = false;
4
5      A(DeviceClass cl, String s)
6      {
7          super(cl, s);
8          constructed = true;
9          ...
10          init_device();
11      }
12
13      public void init_device()
14      {
15          if (constructed == false)
16              {
17                  return;
18              }
19              super.init_device();
20              ...
21          }
22      }
23  

CHAPTER 8. WRITING A TANGO DEVICE SERVER

8.7.2.3 Writing B class specific command

Noting special here. Write these classes as usual

8.7.2.4 Redefining A class command

It is possible to redefine a command which already exist in class A only if the command is created using the inheritance model (but keeping its input and output argument types). The method which really execute the class A command is a method implemented in the A class. With Java, it is possible to redefine all methods except those which are declared as “final”, Therefore, in class B, you can redefine the method executing the command and implement it following the needs of the B class. The following is an example for a command xxx which is programmed to call a my_cmd method.11

```java
1 public class A extends DeviceImpl implements TangoConst
2 {
3     public void my_cmd(long input)
4     {
5         }
6     }
7
8 public class B extends A implements TangoConst
9 {
10     public void my_cmd(long input)
11     {
12         }
13     }
```

Line 3: The my_cmd method is defined in class A
Line 10: The my_cmd method is redefined in class B

Inside the device pattern, the device object is created as an instance of class B12. Java will call the my_cmd method of the B class when the command is received. It is still possible to call the my_cmd method of the A class with the help of the Java “super” keyword inside the code of the my_cmd method of the B class.

8.7.3 Using another device pattern implementation within the same server

It is often necessary that inside the same device server, a method executing a command needs a command of another class to be executed. For instance, a device pattern implementation for a

---

11 In the command execute method
12 By the device factory method of the BClass class
device driven by a serial line class can use the command offered by a serial line class embedded within the same device server process. To execute one of the command (or any other CORBA operations/attributes) of the serial line class, just call it as a normal client will do by using one instance of the DeviceProxy class. The ORB will recognize that all the devices are inside the same process and will execute calls as a local calls. To create the DeviceProxy class instance, the only thing you need to know is the name of the device you gave to the serial line device. Retrieving this could be easily done by a Tango device property. The DeviceProxy class is fully described in chapters related to the Java or C++ Tango Application Programming Interface (API)
Chapter 9

Advanced features

9.1 Attribute alarms

Each Tango attribute two several alarms. These alarms are:

- A four thresholds level alarm
- The read different than set (RDS) alarm

9.1.1 The level alarms

This alarm is defined for all Tango attribute read type and for numerical data type. The action of this alarm depend on the attribute value when it is read:

- If the attribute value is below or equal the attribute configuration min_alarm parameter, the attribute quality factor is switched to Tango::ATTR_ALARM and if the device state is Tango::ON, it is switched to Tango::ALARM.

- If the attribute value is below or equal the attribute configuration min_warning parameter, the attribute quality factor is switched to Tango::ATTR_WARNING and if the device state is Tango::ON, it is switched to Tango::ALARM.

- If the attribute value is above or equal the attribute configuration max_warning parameter, the attribute quality factor is switched to Tango::ATTR_ALARM and if the device state is Tango::ON, it is switched to Tango::ALARM.

- If the attribute value is above or equal the attribute configuration max_alarm parameter, the attribute quality factor is switched to Tango::ATTR_ALARM and if the device state is Tango::ON, it is switched to Tango::ALARM.

If the attribute is a spectrum or an image, then the alarm is set if any one of the attribute value satisfies the above criterium. By default, these four parameters are not defined and no check will be done.

The following figure is a drawing of attribute quality factor and device state values function of the attribute value.
CHAPTER 9. ADVANCED FEATURES

If the min_warning and max_warning parameters are not set, the attribute quality factor will simply change between Tango::ATTR_ALARM and Tango::ATTR_VALID function of the attribute value.

9.1.2 The Read Different than Set (RDS) alarm

This alarm is defined only for attributes of the Tango::READ_WRITE and Tango::READ_WITH_WRITE read/write type and for numerical data type. When the attribute is read (or when the device state is requested), if the difference between its read value and the last written value is something more than or equal to an authorized delta and if at least a certain amount of milliseconds occurs since the last write operation, the attribute quality factor will be set to Tango::ATTR_ALARM and if the device state is Tango::ON, it is switched to Tango::ALARM. If the attribute is a spectrum or an image, then the alarm is set if any one of the attribute value's satisfies the above criterion. This alarm configuration is done with two attribute configuration parameters called delta_val and delta_t. By default, these two parameters are not defined and no check will be done.

9.2 Device polling

9.2.1 Introduction

Each tango device server automatically have a separate polling thread. Polling a device means periodically executing command on a device (or reading device attribute) and storing the results (or the thrown exception) in a polling buffer. The aim of this polling is threefold:

- Speed-up response time for slow device
- Get a first-level history of device command output or attribute value
- Be the data source for the Tango event system

Speeding-up response time is achieved because the command_inout CORBA operation is able to get its data from the polling buffer or from the a real access to the device. For “slow” device, getting the data from the buffer is much faster than accessing the device. Returning a first-level command output history (or attribute value history) to a client is possible due to the polling buffer which is managed as a circular buffer. The history is the contents of this circular buffer. Obviously, the history depth is limited to the depth of the circular buffer. The polling is also the data source for the event system because detecting an event means being able to regularly read the data, memorize it and declaring that it is an event after some comparison with older values.

9.2.2 Configuring the polling system

It is possible to configure the polling in order to poll:

- Any command which does not need input parameter
CHAPTER 9. ADVANCED FEATURES

- Any attribute

Configuring the polling is done by sending command to the device server administration device automatically implemented in every device server process. Seven commands are dedicated to this feature. These commands are

**AddObjPolling** It add a new object (command or attribute) to the list of object(s) to be polled. It is also with this command that the polling period is specified.

**RemObjPolling** To remove one object (command or attribute) from the polled object(s) list

**UpdObjPollingPeriod** Change one object polling period

**StartPolling** Starts polling for the whole process

**StopPolling** Stops polling for the whole process

**PolledDevice** Allow a client to know which device are polled

**DevPollStatus** Allow a client to precisely knows the polling status for a device

All the necessary parameters for the polling configuration are stored in the Tango database. Therefore, the polling configuration is not lost after a device server process stop and restart (or after a device server process crash!)

It is also possible to automatically poll a command (or an attribute) without sending command to the device server administration device. This request some coding (a method call) in the device server software during the command or attribute creation. In this case, for every devices supporting this command or this attribute, polling will automatically start at the first request to read data from the polling buffer. It is possible to stop this behavior on a device basis by sending a RemObjPolling command to the device server administration device. The following piece of code shows how the source code should be written.

```c++
1 2 void DevTestClass::command_factory()
3 {
4    ...  
5        command_list.push_back(new IOStartPoll("IOStartPoll",
6            Tango::DEV_VOID,
7            Tango::DEV_LONG,
8            "Void",
9            "Constant number");
10        command_list.back()->set_polling_period(400);
11    ...
12 }
13
14 void DevTestClass::attribute_factory(vector<Tango::Attr *> &att_list)
15 {
16    ...  
17        att_list.push_back(new Tango::Attr("String_attr",
18            Tango::DEV_STRING,
19            Tango::READ));
20        att_list.back()->set_polling_period(250);
21    ...
22 }
23 ```
A polling period of 400 mS is set for the command called “IOStartPoll” at line 10 with the set_polling_period method of the Command class. Therefore, for a device of this class, the polling thread will start polling its IOStartPoll command when the first request to get the command result from the polling buffer is received except if a RemObjPolling indicating this device and the IOStartPoll command has already been received by the device server administration device. This is exactly the same behavior for attribute. The polling period for attribute called “String_attr” is defined at line 20.

9.2.3 Reading data from the polling buffer

For a polled command or a polled attribute, a client has three possibilities to get command result or attribute value (or the thrown exception):

- From the device itself
- From the polling buffer
- From the polling buffer first and from the device if data in the polling buffer are invalid or if the polling is badly configured.

The choice is done during the command_inout CORBA operation by positioning one of the operation parameter. When reading data from the polling buffer, several error cases are possible:

- The data in the buffer are not valid any more. Every time data are requested from the polling buffer, a check is done between the client request date and the date when the data were stored in the buffer. An exception is thrown if the delta is greater than the polling period multiplied by a “too old” factor. This factor has a default value and is up-datable via a device property. This is detailed in the reference part of this manual.
- The polling is correctly configured but there is no data yet in the polling buffer.

9.2.4 Retrieving command/attribute result history

The polling thread stores the command result or attribute value in circular buffers. It is possible to retrieve an history of the command result (or attribute value) from these polling buffers. Obviously the history is limited by the depth of the circular buffer. For commands, a CORBA operation called command_inout_history_2 allows this retrieval. The client specifies the command name and the record number he want to retrieve. For each record, the call returns the date when the command was executed, the command result or the exception stack in case of the command failed when it was executed by the polling thread. In such a case, the exception stack is sent as a structure member and not as an exception. The same thing is available for attribute. The CORBA operation name is read_attribute_history_2. For these two calls, there is no check done between the call date and the record date in contrary of the call to retrieve the last command result (or attribute value).

9.2.5 Externally triggered polling (only for C++ device server)

Sometimes, rather than polling a command or an attribute regularly with a fixed period, it is more interesting to "manually" decides when the polling must occurs. The Tango polling system also supports this kind of usage. This is called externally triggered polling. To define one attribute (or command) as externally triggered, simply set its polling period to 0. This can be done with the device server administration device AddObjPolling or UpdObjPollingPeriod command. Once
in this mode, the attribute (or command) polling is triggered with the `trigger_cmd_polling()` method or `trigger_attr_polling()` method of the Util class. The following piece of code shows how this method could be used for one externally triggered command.

```cpp
1     ..... 
2     
3     string ext_polled_cmd("MyCmd");
4     Tango::DeviceImpl *device = .....;
5     
6     Tango::Util *tg = Tango::Util::instance();
7     
8     tg->trigger_cmd_polling(device, ext_polled_cmd);
9     
10    ..... 
```

line 3: The externally polled command name  
line 4: The device object  
line 8: Trigger polling of command MyCmd

### 9.2.6 Filling polling buffer (only for C++ device server)

Some hardware to be interfaced already returned an array of pair value, timestamp. In order to be read with the `command_inout_history` or `read_attribute_history` calls, this array has to be transferred in the attribute or command polling buffer. This is possible only for attribute or command configured in the externally triggered polling mode. Once in externally triggered polling mode, the attribute (or command) polling buffer is filled with the `fill_cmd_polling_buffer()` method (or `fill_attr_polling_buffer()` method) of the Util class. For command, the user uses a template class called `TiedCmdData` for each element of the command history. Each element is stored in a stack in one instance of a template class called `CmdHistoryStack`. This object is one of the argument of the `fill_cmd_polling_buffer()` method. Obviously, the stack depth cannot be larger than the polling buffer depth. See A.1.4 to learn how the polling buffer depth is defined. The same way is used for attribute with the `TiedAttrData` and `AttrHistoryStack` template classes. These classes are documented in [8]. The following piece of code fills the polling buffer for a command called MyCmd which is already in externally triggered mode. It returns a `DevVarLongArray` data type with three elements. This example is not really something you will find in a real hardware interface. It is only to demonstrate the `fill_cmd_polling_buffer()` method usage. Error management has also been removed.

```cpp
1     ..... 
2     
3     Tango::DevVarLongArray dvla_array[4];
4     
5     for(int i = 0; i < 4; i++)
6     {
7            dvla_array[i].length(3);
8            dvla_array[i][0] = 10 + i;
9            dvla_array[i][1] = 11 + i;
10           dvla_array[i][2] = 12 + i;
11     }
```
Tango::CmdHistoryStack<DevVarLongArray> chs;
chs.length(4);

for (int k = 0; k < 4; k++)
{
    time_t when = time(NULL);
    Tango::TimedCmdData<DevVarLongArray> tcd(&dvla_array[k], when);
    chs.push(tcd);
}

Tango::Util *tg = Tango::Util::instance();
string cmd_name("MyCmd");
DeviceImpl *dev = ....;
tg->fill_cmd_polling_buffer(dev, cmd_name, chs);

....

Line 3-11: Simulate data coming from hardware
Line 13-14: Create one instance of the CmdHistoryStack class and reserve space for one history of 4 elements
Line 16-17: A loop on each history element
Line 18: Get date (hardware simulation)
Line 20: Create one instance of the TimedCmdData class with data and date
Line 21: Store this command history element in the history stack. The element order will be the insertion order whatever the element date is.
Line 28: Fill command polling buffer

After one execution of this code, a command_inout_history() call will return one history with 4 elements. The first array element of the oldest history record will have the value 10. The first array element of the newest history record will have the value 13. A command_inout() call with the data source parameter set to CACHE will return the newest history record (ie an array with values 13, 14 and 15). A command_inout() call with the data source parameter set to DEVICE will return what is coded is the command method. If you execute this code a second time, a command_inout_history() call will return an history of 8 elements.

The next example fills the polling buffer for an attribute called MyAttr which is already in externally triggered mode. It is a scalar attribute of the DevString data type. This example is not really something you will find in a real hardware interface. It is only to demonstrate the fill_attr_polling_buffer() method usage with memory management issue. Error management has also been removed.

....

AttrHistoryStack<DevString> ahs;
ahs.length(3);

for (int k = 0; k < 3; k++)
{
    time_t when = time(NULL);

DevString *ptr = new DevString[1];
ptr = CORBA::string_dup("Attr history data");
TimedAttrData<DevString> tad(ptr, Tango::ATTR_VALID, true, when);

ars.push(tad);
}
Tango::Util *tg = Tango::Util::instance();
string attr_name("MyAttr");
DeviceImpl *dev = ....;
tg->fill_attr_polling_buffer(dev, attr_name, ars);
.....

Line 3-4: Create one instance of the AttrHistoryStack class and reserve space for an history with 3 elements
Line 6-7: A loop on each history element
Line 8: Get date (hardware simulation)
Line 10-11: Create a string. Note that the DevString object is created on the heap
Line 13: Create one instance of the TimedAttrData class with data and date requesting the memory to be released.
Line 14: Store this attribute history element in the history stack. The element order will be the insertion order whatever the element date is.
Line 21: Fill command polling buffer
It is not necessary to return the memory allocated at line 10. The fill_attr_polling_buffer() method will do it for you.

9.3 Threading

When used with C++, Tango used omniORB as underlying ORB. This CORBA implementation is a threaded implementation and therefore a C++ Tango device server or client are multi-threaded processes.

9.3.1 C++ device server process

A classical Tango device server without any connected clients has five threads (six with Linux). These threads are:

1. The main thread waiting in the ORB main loop
2. An ORB implementation thread (the POA thread)
3. The ORB scavanger thread
4. The signal thread
5. The polling thread

Linux specific: On top of that, there is a sixth thread which is the Linux thread manager. If you type a "ps" command, you will see six "processes". The signal thread is the fifth one and its PID is the PID which should be used when sending signal to the device server process.
A new thread is started for each connected client. Device server are mostly used to interface hardware which most of the time does not support multi-threaded access. Therefore, all remote calls executed from a client are serialized within the device server code by using mutual exclusion. See chapter 9.3.1.1 on which serialization model are available. In order to limit thread number, the underlying ORB (omniORB) is configured to shutdown threads dedicated to client if the connection is inactive for more than 3 minutes. To also limit thread number, the ORB is configured to create one thread per connection up to 35 threads. When this level is reached, the threading model is automatically switch to a "thread pool" model with up to 50 threads. If the number of threads decrease down to 30, the threading model will return to "thread per connection" model.

If you are using event, the event system for its internal heartbeat system periodically (every 200 seconds) send a command to the device server administration device. As explained above, a thread is created to execute these command. The omniORB scavenger will terminate this thread before the next event system heartbeat command arrives. For example, if you have a device server with three connected clients using only event, the process thread number will permanently change between 5 and 8 threads (6 and 9 under Linux).

### 9.3.1.1 Serialization model within a device server

Four serialization models are available within a device server. These models protect all requests coming from the network but also requests coming from the polling thread. These models are:

1. Serialization by device. All access to the same device are serialized. As an example, let's take a device server implementing one class of device with two instances (dev1 and dev2). Two clients are connected to these devices (client1 and client2). Client2 will not be able to access dev1 if client1 is using it. Nevertheless, client2 is able to access dev2 while client1 access dev1 (There is one mutual exclusion object by device)

2. Serialization by class. With non multi-threaded legacy software, the preceding scenario could generate problem. In this mode of serialization, client2 is not able to access dev2 while client1 access dev1 because dev2 and dev1 are instances of the same class (There is one mutual exclusion object by class)

3. Serialization by process. This is one step further than the previous case. In this mode, only one client can access any device embedded within the device server at a time. There is only one mutual exclusion object for the whole process)

4. No serialization. This is an exotic kind of serialization and should be used with extreme care only with device which are fully thread safe. In this model, most of the device access are not serialized at all. Due to Tango internal structure, the get_attribute_config, set_attribute_config, read_attributes and write_attributes CORBA calls are still protected. Reading the device state and status via commands or via CORBA attribute is also protected.

By default, every Tango device server is in serialization by device mode. A method of the Tango::Util class allows to change this default behavior.
```cpp
#include <tango.h>

int main(int argc, char *argv[]) {

    try {
        Tango::Util *tg = Tango::Util::init(argc, argv);
        tg->set_serial_model(Tango::BY_CLASS);
        tg->server_init();
        cout << "Ready to accept request" << endl;
        tg->server_run();
    } catch (bad_alloc) {
        cout << "Can't allocate memory!!!" << endl;
        cout << "Exiting" << endl;
    } catch (CORBA::Exception &e) {
        Tango::Except::print_exception(e);
        cout << "Received a CORBA::Exception" << endl;
        cout << "Exiting" << endl;
    }
    return(0);
}
```

The serialization model is set at line 11 before the server is initialized and the infinite loop is started. See [8] for all details on the methods to set/get serialization model.

### 9.3.2 C++ client process

Clients are also multi threaded processes. The underlying C++ ORB (omniORB) try to keep system resources to a minimum. To decrease process file descriptors usage, each connection to server is automatically closed if it is idle for more than 2 minutes and automatically re-opened when needed. A dedicated thread is spawned by the ORB to manage this automatic closing connection (the scavenger thread).

Therefore, a Tango client has two threads (3 under Linux) which are:

1. The main thread
2. The ORB scavenger thread

If the client is using the event system and as Tango is using the event push-push model, it has to be a server for the Notification service. This increases the number of thread. The client now has 6 threads (7 under Linux) which are:
1. The main thread
2. The ORB scavenger thread
3. The main server ORB loop thread
4. The server POA thread
5. The thread created by omniORB has soon has an event has been sent by a Notification service. This thread will execute the callbacks
6. A Tango internal event system thread (called the KeepAliveThread)

9.4 Generating events in a device server

The server is at the origin of events. It will fire events as soon as they occur. Standard events (change, periodic, quality, archive, etc.) are detected automatically in the polling thread and fired as soon as they are detected. For the standard events there is no api. For non-standard events a single call exists for pushing the data to the CORBA Notification Service (omniNotify). Clients who are subscribed to this event have to know what data type is in the DeviceAttribute and unpack it accordingly.

To push non-standard events, use the following api call available to all device servers:

```cpp
DeviceImpl::push_event(
    vector<string> &filterable_names,
    vector<double> &filterable_data,
    Attribute &att)
```

where `filterable_names` and `filterable_data` represent any filterable data which can be used by clients to filter on, and `att` is the attribute object. Note that this call consumed some memory used to store the attribute value. The attribute value has to be re-set (using `Attribute::set_value()` method) after the event has been pushed if the attribute value inside the Attribute object is still needed.

Here is a typical example of what a server will need to do to send events. We are in the read method of the "Sinusoide" attribute. This attribute is readable as any other attribute but an event is sent if its value is positive when it is read. On top of that, this event is sent with one filterable field called "value" which is set to the attribute value.

```cpp
1  void MyClass::read_Sinusoide(Tango::Attribute &attr)
2  {
3     ...
4     struct timeval tv;
5     gettimeofday(&tv, NULL);
6     sinusoide = 100 * sin( 2 * 3.14 * frequency * tv.tv_sec);
7     attr.set_value(&sinusoide);
8
9     if (sinusoide >= 0)
10        {
11            vector<string> filterable_names;
12            vector<double> filterable_value;
13
14            filterable_names.push_back("value");
15            filterable_value.push_back((double)sinusoide);
16        }
```
CHAPTER 9. ADVANCED FEATURES

push_event(filterable_names, filterable_value, attr);
attr.set_value(&sinusoid);
}

line 7: The attribute is set in the Attribute object
line 14-15: The filter pair name/value is initialised
line 17-19: The event is pushed
line 21: The push_event() call has consumed some memory when sending the attribute to the event system. It is needed to re-set its value in the Attribute object.

9.5 Memorized attribute

It is possible to ask Tango to store in its database the last written value for attribute of the SCALAR data format and obviously only for READ_WRITE or READ_WITH_WRITE attribute. This is fully automatic. During device startup phase, for all device memorized attributes, the value written in the database is fetched and a write_attribute call is generated to apply this value. The following piece of code shows how the source code should be written to set an attribute as memorized.

void DevTestClass::attribute_factory(vector<Tango::Attr*> &att_list)
{
    ... 
    att_list.push_back(new String_attrAttr());
    att_list.back()->set_memorized();
    ...
}

Line 4: The attribute to be memorized is created and inserted in the attribute vector. Line 5: The set_memorized() method of the attribute base class is called to define the attribute as memorized.

9.6 Device server using file as database

For device servers not able to access the Tango database (most of the time due to network route or security reason), it is possible to start them using file instead of a real database. This is done via the device server

-file=<file name>

command line option. In this case,
CHAPTER 9. ADVANCED FEATURES

- Getting, setting and deleting class properties
- Getting, setting and deleting device properties
- Getting, setting and deleting class attribute properties
- Getting, setting and deleting device attribute properties

are handled using the specified file instead of the Tango database. The file is an ASCII file and follows a well-defined syntax with predefined keywords. The simplest way to generate the file for a specific device server is to use the Jive application. See [21] to get Jive documentation. The Tango database is not only used to store device configuration parameters, it is also used to store device network access parameter (the CORBA IOR). To allow an application to connect to a device hosted by a device server using file instead of database, you need to start it on a pre-defined port, and you must use one of the underlying ORB option called endpoint like

```bash
myserver myinstance_name -file=/tmp/MyServerFile -ORBendPoint giop:tcp:<port number>
```

to start your device server. The device name passed to the client application must also be modified in order to reflect the non-database usage. See C.1 to learn about Tango device name syntax. Nevertheless, using this Tango feature prevents some other features to be used:

- No check that the same device server is running twice.
- No device or attribute alias name.
- In case of several device servers running on the same host, the user must manually manage a list of already used network port.

9.7 Device server without database

In some very specific cases (Running a device server within a lab during hardware development...), it could be very useful to have a device server able to run even if there is no database in the control system. Obviously, running a Tango device server without a database means losing Tango features. The lost features are:

- No check that the same device server is running twice.
- No device configuration via properties.
- No event generated by the server.
- No memorized attributes
- No device attribute configuration via the database.
- No check that the same device name is used twice within the same control system.
- In case of several device servers running on the same host, the user must manually manage a list of already used network port.

To run a device server without a database, the -noDB command line option must be used. One problem when running a device server without the database is to pass device name(s) to the device server. Within Tango, it is possible to define these device names at two different levels:

1. At the command line with the -dlist option: In case of device server with several device pattern implementation, the device name list given at command line is only for the last device pattern created in the class_factory() method. In the device name list, the device name separator is the comma character.
2. At the device pattern implementation level: In the class inherited from the Tango::DeviceClass
   class via the re-definition of a well defined method called device_name_factory()

If none of these two possibilities is used, the tango core classes defined one default device name
for each device pattern implementation. This default device name is NoName. Device definition
at the command line has the highest priority.

9.7.1 Example of device server started without database usage

Without database, you need to start a Tango device server on a pre-defined port, and you must
use one of the underlying ORB option called endPoint like

    myserver myinstance_name -ORBendPoint giop://<port number> -nodb -dblist a/b/c

The following is two examples of starting a device server not using the database when the
device_name_factory() method is not re-defined.

- StepperMotor et -nodb -dlist id11/motor/1,id11/motor/2
  This command line starts the device server with two devices named id11/motor/1 and
  id11/motor/2

- StepperMotor et -nodb
  This command line starts a device server with one device named NoName

When the device_name_factory() method is re-defined within the StepperMotorClass class.

```cpp
void StepperMotorClass::device_name_factory(vector<string> &list)
{
    list.push_back("sr/cav-tuner/1");
    list.push_back("sr/cav-tuner/2");
}
```

- StepperMotor et -nodb
  This command starts a device server with two devices named sr/cav-tuner/1 and sr/cav-
tuner/2.

- StepperMotor et -nodb -dlist id12/motor/1
  Starts a device server with only one device named id12/motor/1

9.7.1.1 Java device server without the database

It is also possible to start a Java device server without the database using exactly the principle
described in the above lines. Nevertheless, a Java device server process retrieves its list of device
pattern implementation from the database! Therefore, a add_class() method is defined in the
Java Util class and the main method must be updated.

```java
package StepperMotor
import java.util.*;
import org.omg.CORBA.*;
import fr.earf.Tango.*;
```
import fr.earf.TangoDs,*;

public class StepperMotor extends DeviceImpl implements TangoConst {
    public static void main(String[] argv)
    {
        try
        {
            Util tg = Util.init(argv, "StepperMotor");
            tg.add_class("StepperMotor");
            tg.server_init();
            System.out.println("Ready to accept request");
            tg.server_run();
        }
        catch (OutOfMemoryError ex)
        {
            System.err.println("Can’t allocate memory !!!!!");
            System.err.println("Exiting");
        }
        catch (UserException ex)
        {
            Except.print_exception(ex);
            System.err.println("Received a CORBA user exception");
            System.err.println("Exiting");
        }
        catch (SystemException ex)
        {
            Except.print_exception(ex);
            System.err.println("Received a CORBA system exception");
            System.err.println("Exiting");
        }
        System.exit(-1);
    }
}

The add_class() method is used at line 17 before the device pattern(s) implementation initialization.

9.7.1.2 Start a java device server without database

Without database, you need to start a Tango device server on a pre-defined port, and you must use one of the underlying ORB option OAPort like

    java -DOAPort=<port number> myserver myinstance_name -nodb -dlist
    id11/motor/1/id11/motor/2
9.7.2 Connecting client to device within a device server started without database

In this case, the host and port on which the device server is running are part of the device name. If the device name is a/b/c, the host is mycomputer and the port 1234, the device name to be used by client is

mycomputer:1234/a/b/c

See appendix C.1 for all details about Tango object naming.

9.8 Multiple database servers within a Tango control system

Tango uses MySQL as database and allows access to this database via a specific Tango device server. It is possible for the same Tango control system to have several Tango database servers. The host name and port number of the database server is known via the TANGO_HOST environment variable. If you want to start several database servers in order to prevent server crash, use the following TANGO_HOST syntax

TANGO_HOST=<host_1>:<port_1>,<host_2>:<port_2>,<host_3>:<port_3>

All calls to the database server will automatically switch to a running servers in the given list if the one used dies.
Appendix A

Reference part

This chapter is only part of the TANGO device server reference guide. To get reference documentation about the C++ library classes, see [8]. To get reference documentation about the Java classes, also see [8].

A.1 Device parameter

A black box, a device description field, a device state and status are associated with each TANGO device.

A.1.1 The device black box

The device black box is managed as a circular buffer. It is possible to tune the buffer depth via a device property. This property name is

\[
\text{device name->blackbox\_depth}
\]

A default value is hard-coded to 25 if the property is not defined. This black box depth property is retrieved from the Tango property database during the device creation phase.

A.1.2 The device description field

There are two ways to initialise the device description field.

- At device creation time. Some constructors of the DeviceImpl class supports this field as parameter. If these constructor are not used, the device description field is set to a default value which is a Tango device.

- With a property. A description field defines with this method overrides a device description defined at construction time. The property name is

\[
\text{device name->description}
\]

A.1.3 The device state and status

Some constructors of the DeviceImpl class allows the initialisation of device state and/or status or device creation time. If these fields are not defined, a default value is applied. The default state is Tango::UNKNOWN, the default status is Not Initialised.
A.1.4 The device polling

Four device properties allow the polling tuning. These properties are described in the following table:

<table>
<thead>
<tr>
<th>Property name</th>
<th>property rule</th>
<th>default value</th>
</tr>
</thead>
<tbody>
<tr>
<td>poll_ring_depth</td>
<td>Polling buffer depth</td>
<td>10</td>
</tr>
<tr>
<td>cmd_poll_ring_depth</td>
<td>Cmd polling buffer depth</td>
<td></td>
</tr>
<tr>
<td>attr_poll_ring_depth</td>
<td>Attr polling buffer depth</td>
<td></td>
</tr>
<tr>
<td>poll_old_factor</td>
<td>Data too old factor</td>
<td>4</td>
</tr>
</tbody>
</table>

The rule of the poll_ring_depth property is obvious. It defines the polling ring depth for all the device polled command(s) and attribute(s). Nevertheless, when filling the polling buffer via the fill_cmd_polling_buffer() (or fill_attr_polling_buffer()) method, it could be helpful to define specific polling ring depth for a command (or an attribute). This is the rule of the cmd_poll_ring_depth and attr_poll_ring_depth properties. For each polled object with specific polling depth (command or attribute), the syntax of this property is the object name followed by the ring depth (ie State,20,Status,15). If one of these properties is defined, for the specific command or attribute, it will overwrite the value set by the poll_ring_depth property. The poll_old_factor property allows the user to tune how long the data recorded in the polling buffer are valid. Each time some data are read from the polling buffer, a check is done between the date when the data were recorded in the polling buffer and the date when the user request these data. If the interval is greater than the object polling period multiply by the value of the poll_old_factor factory, an exception is returned to the caller. These two properties are defined at device level and therefore, it is not possible to tune this parameter for each polled object (command or attribute).

Four other properties are used by the Tango core classes to manage the polling thread. These properties are:

- polled_cmd to memorize the name of the device polled command
- polled_attr to memorize the name of the device polled attribute
- non_auto_pollled_cmd to memorize the name of the command which should not be polled automatically at the first request
- non_auto_pollled_attr to memorize the name of the attribute which should not be polled automatically at the first request

You don’t have to change these properties values by yourself. They are automatically created/modified/deleted by Tango core classes.

A.1.5 The device logging

The Tango Logging Service (TLS) uses device properties to control device logging at startup (static configuration). These properties are described in the following table:

<table>
<thead>
<tr>
<th>Property name</th>
<th>property rule</th>
<th>default value</th>
</tr>
</thead>
<tbody>
<tr>
<td>logging_level</td>
<td>Initial device logging level</td>
<td>WARN</td>
</tr>
<tr>
<td>logging_target</td>
<td>Initial device logging target</td>
<td>No default</td>
</tr>
<tr>
<td>logging_roll</td>
<td>Logging rolling file threshold</td>
<td>2 Mega bytes</td>
</tr>
<tr>
<td>logging_path</td>
<td>Logging file path</td>
<td>/tmp/tango or C:/tango (win32)</td>
</tr>
</tbody>
</table>
• The logging_level property controls the initial logging level of a device. Its set of possible values is: "OFF", "FATAL", "ERROR", "WARN", "INFO" or "DEBUG". This property is overwritten by the verbose command line option (-v).

• The logging_target property is a multi-valued property containing the initial target list. Each entry must have the following format: target_type:target_name (where target_type is one of the supported target types and target_name, the name of the target). Supported target types are: console, file and device. For a device target, target_name must contain the name of a log consumer device (as defined in A.7). For a file target, target_name is the name of the file to log to. If omitted the device's name is used to build the file name (domain_family_member.log). Finally, target_name is ignored in the case of a console target. The TLS does not report any error occurred while trying to setup the initial targets.

  – Logging_target property example:

    logging_target = ["console", "file": /home/me/mydevice.log", "device:tmp/log/1"]

    In this case, the device will automatically logs to the standard output, to its default file (which is something like domain_family_member.log), to a file named mydevice.log and located in /home/me. Finally, the device logs are also sent to a log consumer device named tmp/log/1.

• The logging_rft property specifies the rolling file threshold (rft), of the device's file targets. This threshold is expressed in Kb in the range [500, 20480]. When the size of a log file reaches the so-called rolling-file-threshold (rft), it is backed up as "current_log_file_name" + "_1" and a new current_log_file_name is opened. Obviously, there is only one backup file at a time (i.e. any existing backup is destroyed before the current log file is backed up). The default threshold is 2Mb, the minimum is 500 Kb and the maximum is 20 Mb.

• The logging_path property overwrites the TANGO_LOG_PATH environment variable. This property can only be applied to a DServer class device and has no effect on other devices.

A.2 Device attribute

Attribute are configured with two kind of parameters: Parameters hard-coded in source code and modifiable parameters

A.2.1 Hard-coded device attribute parameters

Seven attribute parameters are defined at attribute creation time in the device server source code. Obviously, these parameters are not modifiable except with a new source code compilation. These parameters are

<table>
<thead>
<tr>
<th>Parameter name</th>
<th>Parameter description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>Attribute name</td>
</tr>
<tr>
<td>data_type</td>
<td>Attribute data type</td>
</tr>
<tr>
<td>data_format</td>
<td>Attribute data format</td>
</tr>
<tr>
<td>writable</td>
<td>Attribute read/write type</td>
</tr>
</tbody>
</table>
A.2.1.1 The Attribute data type

Eight data types are supported. These data types are

- Tango::DevBoolean
- Tango::DevShort
- Tango::DevLong
- Tango::DevFloat
- Tango::DevDouble
- Tango::DevUChar
- Tango::DevUShort
- Tango::DevString

A.2.1.2 The attribute data format

Three data format are supported for attribute

<table>
<thead>
<tr>
<th>Format</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Tango::SCALAR</td>
<td>The attribute value is a single number</td>
</tr>
<tr>
<td>Tango::SPECTRUM</td>
<td>The attribute value is a one dimension number</td>
</tr>
<tr>
<td>Tango::IMAGE</td>
<td>The attribute value is a two dimension number</td>
</tr>
</tbody>
</table>

A.2.1.3 The max_dim_x and max_dim_y parameters

These two parameters defined the maximum size for attributes of the SPECTRUM and IMAGE data format.

<table>
<thead>
<tr>
<th>data format</th>
<th>max_dim_x</th>
<th>max_dim_y</th>
</tr>
</thead>
<tbody>
<tr>
<td>Tango::SCALAR</td>
<td>1</td>
<td>0</td>
</tr>
<tr>
<td>Tango::SPECTRUM</td>
<td>User Defined</td>
<td>0</td>
</tr>
<tr>
<td>Tango::IMAGE</td>
<td>User Defined</td>
<td>User Defined</td>
</tr>
</tbody>
</table>
APPENDIX A. REFERENCE PART

For attribute of the Tango::IMAGE data format, all the data are also returned in a one dimension array. The first array is value[0][0], array element X is value[0][X-1]; array element X+1 is value[1][0] and so forth.

A.2.1.4 The attribute read/write type
Tango supports four kind of read/write attribute which are:

- Tango::READ for read only attribute
- Tango::WRITE for writable attribute
- Tango::READ_WRITE for attribute which can be read and write
- Tango::READ_WITH_WRITE for a readable attribute associated to a writable attribute

(For a power supply device, the current really generated is not the wanted current. To handle this, two attributes are defined which are generated_current and wanted_current. The wanted_current is a Tango::WRITE attribute. When the generated_current attribute is read, it is very convenient to also get the wanted_current attribute. This is exactly what the Tango::READ_WITH_WRITE attribute is doing)

When read, attribute values are always returned within an array even for scalar attribute. The length of this array and the meaning of its elements is detailed in the following table for scalar attribute.

<table>
<thead>
<tr>
<th>Name</th>
<th>Array length</th>
<th>Array[0]</th>
<th>Array[1]</th>
</tr>
</thead>
<tbody>
<tr>
<td>Tango::READ</td>
<td>1</td>
<td>Read value</td>
<td></td>
</tr>
<tr>
<td>Tango::WRITE</td>
<td>1</td>
<td>Last write value</td>
<td></td>
</tr>
<tr>
<td>Tango::READ_WRITE</td>
<td>2</td>
<td>Read value</td>
<td>Last write value</td>
</tr>
<tr>
<td>Tango::READ_WITH_WRITE</td>
<td>2</td>
<td>Read value</td>
<td>Associated attributelast write value</td>
</tr>
</tbody>
</table>

When a spectrum or image attribute is read, it is possible to code the device class in order to send only some part of the attribute data (For instance only a Region Of Interest for an image) but never more than what is defined by the attribute configuration parameters max_dim_x and max_dim_y. The number of data sent is also transferred with the data and is named dim_x and dim_y. When a spectrum or image attribute is written, it is also possible to send only some of the attribute data but always less than max_dim_x for spectrum and max_dim_x * max_dim_y for image. The following table describe how data are returned for spectrum attribute. dim_x is the data size sent by the server when the attribute is read and dim_x_w is the data size used during the last attribute write call.

<table>
<thead>
<tr>
<th>Name</th>
<th>Array length</th>
<th>Array[0-]&gt;dim_x-1</th>
<th>Array[&gt;dim_x-&gt;dim_x+dim_x]</th>
</tr>
</thead>
<tbody>
<tr>
<td>Tango::READ</td>
<td>dim_x</td>
<td>Read values</td>
<td></td>
</tr>
<tr>
<td>Tango::WRITE</td>
<td>dim_x_w</td>
<td>Last write values</td>
<td></td>
</tr>
<tr>
<td>Tango::READ_WRITE</td>
<td>dim_x+dim_x_w</td>
<td>Read value</td>
<td>Last write values</td>
</tr>
<tr>
<td>Tango::READ_WITH_WRITE</td>
<td>dim_x+dim_x_w</td>
<td>Read value</td>
<td>Associated attributelast write values</td>
</tr>
</tbody>
</table>
The following table describes how data are returned for image attribute. \( \text{dim}_r \) is the data size sent by the server when the attribute is read (\( \text{dim}_x \times \text{dim}_y \)) and \( \text{dim}_w \) is the data size used during the last attribute write call (\( \text{dim}_x \times \text{dim}_y \times \text{dim}_w \)).

<table>
<thead>
<tr>
<th>Name</th>
<th>Array length</th>
<th>Array[0-&gt;dim_r-1]</th>
<th>Array[dim_r-&gt;dim_r+dim_w-1]</th>
</tr>
</thead>
<tbody>
<tr>
<td>Tango::READ</td>
<td>( \text{dim}_r )</td>
<td>Read values</td>
<td></td>
</tr>
<tr>
<td>Tango::WRITE</td>
<td>( \text{dim}_w )</td>
<td>Last write values</td>
<td></td>
</tr>
<tr>
<td>Tango::READ_WRITE</td>
<td>( \text{dim}_r + \text{dim}_w )</td>
<td>Read value</td>
<td>Last write values</td>
</tr>
<tr>
<td>Tango::READ_WRITE_WRITE</td>
<td>( \text{dim}_r + \text{dim}_w )</td>
<td>Read value</td>
<td>Associated attribute values</td>
</tr>
</tbody>
</table>

Until a write operation has been performed, the last write value is initialized to 0 for scalar attribute of the numerical type, to "Not initialized" for scalar string attribute and to true for scalar boolean attribute. For spectrum or image attribute, the last write value is initialized to an array of one element set to 0 for numerical type, to an array of one element set to true for boolean attribute and to an array of one element set to "Not initialized" for string attribute.

A.2.1.5 The associated write attribute parameter

This parameter has a meaning only for attribute with a Tango::READ_WRITE_WRITE read/write type. This is the name of the associated write attribute.

A.2.1.6 The attribute display level parameter

This parameter is only an help for graphical application. It is a C++ enumeration starting at 0 or a final class for Java. The code associated with each attribute display level is defined in the following table (Tango::DispLevel).

<table>
<thead>
<tr>
<th>name</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Tango::OPERATOR</td>
<td>0</td>
</tr>
<tr>
<td>Tango::EXPERT</td>
<td>1</td>
</tr>
</tbody>
</table>

This parameter allows a graphical application to support two types of operation:

- An operator mode for day to day operation
- An expert mode when tuning is necessary

According to this parameter, a graphical application knows if the attribute is for the operator mode or for the expert mode.

A.2.2 Modifiable attribute parameters

Each attribute has a configuration set of 20 modifiable parameters. These can be grouped in three different purposes:

1. General purpose parameters...
2. Alarm related parameters
3. Event related parameters

A.2.2.1 General purpose parameters

Eight attribute parameters are modifiable at run-time via a device call or via the property database.

<table>
<thead>
<tr>
<th>Parameter name</th>
<th>Parameter description</th>
</tr>
</thead>
<tbody>
<tr>
<td>description</td>
<td>Attribute description</td>
</tr>
<tr>
<td>label</td>
<td>Attribute label</td>
</tr>
<tr>
<td>unit</td>
<td>Attribute unit</td>
</tr>
<tr>
<td>standard_unit</td>
<td>Conversion factor to MKSA unit</td>
</tr>
<tr>
<td>display_unit</td>
<td>The attribute unit in a printable form</td>
</tr>
<tr>
<td>format</td>
<td>How to print attribute value</td>
</tr>
<tr>
<td>min_value</td>
<td>Attribute min value</td>
</tr>
<tr>
<td>max_value</td>
<td>Attribute max value</td>
</tr>
</tbody>
</table>

The description parameter describes the attribute. The label parameter is used by graphical application to display a label when this attribute is used in a graphical application. The unit parameter is the attribute value unit. The standard_unit parameter is the conversion factor to get attribute value in MKSA units. Even if this parameter is a number, it is returned as a string by the device get_attribute_config call. The display_unit parameter is the string used by graphical application to display attribute unit to application user.

A.2.2.1.1 The format attribute parameter

This parameter specifies how the attribute value should be printed. It is not valid for string attribute. This format is a string of C++ streams manipulators separated by the ; character. The supported manipulators are:

- fixed
- scientific
- uppercase
- showpoint
- showpos
- setprecision()
- setw()

Their definition are the same than for C++ streams. An example of format parameter is

scientific;uppercase;setprecision(3)

A class called Tango::AttrManip has been written to handle this format string. Once the attribute format string has been retrieved from the device, its value can be printed with

```cpp
cout << Tango::AttrManip(format) << value << endl;
```
A.2.2.1.2 The min_value and max_value parameters

These two parameters have a meaning only for attribute of the Tango::WRITE read/write type and for numerical data type. Trying to set the value of an attribute to something less than or equal to the min_value parameter is an error. Trying to set the value of the attribute to something more or equal to the max_value parameter is also an error. Even if these parameters are numbers, they are returned as strings by the device get_attribute_config() call.

A.2.2.2 The alarm related configuration parameters

Six alarm related attribute parameters are modifiable at run-time via a device call or via the property database.

<table>
<thead>
<tr>
<th>Parameter name</th>
<th>Parameter description</th>
</tr>
</thead>
<tbody>
<tr>
<td>min_alarm</td>
<td>Attribute low level alarm</td>
</tr>
<tr>
<td>max_alarm</td>
<td>Attribute high level alarm</td>
</tr>
<tr>
<td>min_warning</td>
<td>Attribute low level warning</td>
</tr>
<tr>
<td>max_warning</td>
<td>Attribute high level warning</td>
</tr>
<tr>
<td>delta_t</td>
<td>delta time for RDS alarm (mS)</td>
</tr>
<tr>
<td>delta_val</td>
<td>delta value for RDS alarm (absolute)</td>
</tr>
</tbody>
</table>

A.2.2.2.1 The min_alarm and max_alarm parameters

These two parameters have a meaning only for attribute of the Tango::READ, Tango::READ_WRITE and Tango::READ_WITH_WRITE read/write type and for numerical data type. When the attribute is read, if its value is something less than or equal to the min_alarm parameter or if it is something more or equal to the max_alarm parameter, the attribute quality factor will be set to Tango::ATTR_ALARM and if the device state is Tango::ON, it is switched to Tango::ALARM. Even if these parameters are numbers, they are returned as strings by the device get_attribute_config() call.

A.2.2.2.2 The min_warning and max_warning parameters

These two parameters have a meaning only for attribute of the Tango::READ, Tango::READ_WRITE and Tango::READ_WITH_WRITE read/write type and for numerical data type. When the attribute is read, if its value is something less than or equal to the min_warning parameter or if it is something more or equal to the max_warning parameter, the attribute quality factor will be set to Tango::ATTR_WARNING and if the device state is Tango::ON, it is switched to Tango::ALARM. Even if these parameters are numbers, they are returned as strings by the device get_attribute_config() call.

A.2.2.2.3 The delta_t and delta_val parameters

These two parameters have a meaning only for attribute of the Tango::READ_WRITE and Tango::READ_WITH_WRITE read/write type and for numerical data type. They specify if and how the RDS alarm is used. When the attribute is read, if the difference between its read value and the last written value is something more than or equal to the delta_val parameter and if at least delta_val milli seconds occurs since the last write operation, the attribute quality factor will be set to Tango::ATTR_ALARM and if the device state is Tango::ON, it is switched to Tango::ALARM. Even if these parameters are numbers, they are returned as strings by the device
get_attribute_config() call.

A.2.2.3 The event related configuration parameters

Six event related attribute parameters are modifiable at run-time via a device call or via the property database.

<table>
<thead>
<tr>
<th>Parameter name</th>
<th>Parameter description</th>
</tr>
</thead>
<tbody>
<tr>
<td>rel_change</td>
<td>Relative change triggering change event</td>
</tr>
<tr>
<td>abs_change</td>
<td>Absolute change triggering change event</td>
</tr>
<tr>
<td>period</td>
<td>Period for periodic event</td>
</tr>
<tr>
<td>archive_rel_change</td>
<td>Relative change for archive event</td>
</tr>
<tr>
<td>archive_abs_change</td>
<td>Absolute change for archive event</td>
</tr>
<tr>
<td>archive_period</td>
<td>Period for change archive event</td>
</tr>
</tbody>
</table>

A.2.2.3.1 The rel_change and abs_change parameters

Rel_change is an array property with a maximum of 2 values. It specifies the positive and negative relative change of the attribute value w.r.t. the value of the previous change event which will trigger the event. If the attribute is a spectrum or an image then a change event is generated if any one of the attribute value’s satisfies the above criterion. If only one property is specified then it is used for the positive and negative change.

Abs_change is an array property of maximum 2 values. It specifies the positive and negative absolute change of the attribute value w.r.t. the value of the previous change event which will trigger the event. If the attribute is a spectrum or an image then a change event is generated if any one of the attribute value’s satisfies the above criterion. If only one property is specified then it is used for the positive and negative change. If no properties are specified then the relative change is used.

A.2.2.3.2 The periodic period parameter

The minimum time between events (in milliseconds). If no property is specified then a default value of 1 second is used.

A.2.2.3.3 The archive_rel_change, archive_abs_change and archive_period parameters

archive_rel_change is an array property of maximum 2 values which specifies the positive and negative relative change w.r.t. the previous attribute value which will trigger the event. If the attribute is a spectrum or an image then an archive event is generated if any one of the attribute value’s satisfies the above criterion. If only one property is specified then it is used for the positive and negative change. If no properties are specified then a default fo + 10% is used.

archive_abs_change is an array property of maximum 2 values which specifies the positive and negative absolute change w.r.t. the previous attribute value which will trigger the event. If the attribute is a spectrum or an image then an archive event is generated if any one of the attribute value’s satisfies the above criterion. If only one property is specified then it is used for the positive and negative change. If no properties are specified then the relative change is used.

archive_period is the minimum time between archive events (in milliseconds). If no property is specified then a default value of 10 seconds is used.
A.2.3 Setting modifiable attribute parameters

A default value is given to all modifiable attribute parameters by the Tango core classes. Nevertheless, it is possible to modify these values in source code at attribute creation time or via the database. Values retrieved from the database have a higher priority than values given at attribute creation time. The default value set by the Tango core classes are

<table>
<thead>
<tr>
<th>Parameter type</th>
<th>Parameter name</th>
<th>Library default value</th>
</tr>
</thead>
<tbody>
<tr>
<td>general</td>
<td>description</td>
<td>No description</td>
</tr>
<tr>
<td></td>
<td>label</td>
<td>device name/attribute name</td>
</tr>
<tr>
<td></td>
<td>unit</td>
<td>No unit</td>
</tr>
<tr>
<td></td>
<td>standard_unit</td>
<td>No standard unit</td>
</tr>
<tr>
<td></td>
<td>display_unit</td>
<td>No display unit</td>
</tr>
<tr>
<td></td>
<td>format</td>
<td>6 characters with 2 decimal</td>
</tr>
<tr>
<td>alarm</td>
<td>min_value</td>
<td>Not specified</td>
</tr>
<tr>
<td></td>
<td>max_value</td>
<td>Not specified</td>
</tr>
<tr>
<td></td>
<td>min_alarm</td>
<td>Not specified</td>
</tr>
<tr>
<td></td>
<td>max_alarm</td>
<td>Not specified</td>
</tr>
<tr>
<td></td>
<td>min_warning</td>
<td>Not specified</td>
</tr>
<tr>
<td></td>
<td>max_warning</td>
<td>Not specified</td>
</tr>
<tr>
<td></td>
<td>delta_t</td>
<td>Not specified</td>
</tr>
<tr>
<td></td>
<td>delta_val</td>
<td>Not specified</td>
</tr>
<tr>
<td>event</td>
<td>rel_change</td>
<td>Not specified</td>
</tr>
<tr>
<td></td>
<td>abs_change</td>
<td>Not specified</td>
</tr>
<tr>
<td></td>
<td>period</td>
<td>Not specified</td>
</tr>
<tr>
<td></td>
<td>archive_rel_change</td>
<td>Not specified</td>
</tr>
<tr>
<td></td>
<td>archive_abs_change</td>
<td>Not specified</td>
</tr>
<tr>
<td></td>
<td>archive_period</td>
<td>Not specified</td>
</tr>
</tbody>
</table>

It is possible to set modifiable parameters via the database at two levels:

1. At class level
2. At device level. Each device attribute have all its modifiable parameters set to the value defined at class level. If the setting defined at class level is not correct for one device, it is possible to re-define it.

If we take the example of a class called BumperPowerSupply with three devices called sr/bump/1, sr/bump/2 and sr/bump/3 and one attribute called wanted_current. For the first two bumpers, the max_value is equal to 500. For the third one, the max_value is only 400. If the max_value parameter is defined at class level with the value 500, all devices will have 500 as max_value for the wanted_current attribute. It is necessary to re-defined this parameter at device level in order to have the max_value for device sr/bump/3 set to 400.

For the description, label, unit, standard_unit, display_unit and format parameters, it is possible to return them to their default value by setting them to an empty string.

A.3 Device class parameter

A device documentation field is also defined at Tango device class level. It is defined as Tango device class level because each device belonging to a Tango device class should have the same
behaviour and therefore the same documentation. This field is store in the DeviceClass class. It
is possible to set this field via a class property. This property name is

    class name->doc_url

and is retrieved when instance of the DeviceClass object is created. A default value is defined for
this field.

### A.4 The device black box

This black box is a help tool to ease debugging session for a running device server. The TANGO
core software records every device request in this black box. A tango client is able to retrieve the
black box contents with a specific CORBA operation available for every device. Each black box
entry is returned as a string with the following information:

- The date where the request has been executed by the device. The date format is dd/mm/yyyy
  hh24:miss:SS (The last field is the second hundredth number).

- The type of CORBA requests. In case of attributes, the name of the requested attribute
  is returned. In case of operation, the operation type is returned. For “command_inout”
  operation, the command name is returned.

- The client host name

### A.5 Automatically added commands

As already mentioned in this documentation, each Tango device supports at least three commands
which are State, Status and Init. The following array details command input and output data type

<table>
<thead>
<tr>
<th>Command name</th>
<th>Input data type</th>
<th>Output data type</th>
</tr>
</thead>
<tbody>
<tr>
<td>State</td>
<td>void</td>
<td>Tango::DevState</td>
</tr>
<tr>
<td>Status</td>
<td>void</td>
<td>Tango::DevString</td>
</tr>
<tr>
<td>Init</td>
<td>void</td>
<td>void</td>
</tr>
</tbody>
</table>

#### A.5.1 The State command

This command gets the device state (stored in its `device_state` data member) and returns it to
the caller. The device state is a variable of the Tango::DevState type (packed into a CORBA Any
object when it is returned by a command)

#### A.5.2 The Status command

This command gets the device status (stored in its `device_status` data member) and returns it to
the caller. The device status is a variable of the string type.

#### A.5.3 The Init command

This commands re-initialise a device keeping the same network connection. After an Init command
executed on a device, it is not necessary for client to re-connect to the device. This command
first calls the device `delete_device()` method and then execute its `init_device()` method. For C++ device server, all the memory allocated in the `init_device()` method must be freed in the `delete_device()` method. The language device destructor automatically calls the `delete_device()` method.

### A.6 DServer class device commands

As already explained in 8.1.7.2, each device server process has its own Tango device. This device supports the three commands previously described plus 22 commands (for C++ device server, only 20 for Java device server) which are DevRestart, RestartServer, QueryClass, QueryDevice, Kill, QueryWizardClassProperty, QueryWizardDevProperty, the polling related commands which are StartPolling, StopPolling, AddObjPolling, RemObjPolling, UpdObjPollingPeriod, PolledDevice and DevPollStatus, the event related command called EventSubscriptionChange (only for C++) and finally the logging related commands which are AddLoggingTarget, RemoveLoggingTarget, GetLoggingTarget, GetLoggingLevel, SetLoggingLevel, StopLogging and StartLogging. The following table gives all commands input and output data types.

<table>
<thead>
<tr>
<th>Command name</th>
<th>Input data type</th>
<th>Output data type</th>
</tr>
</thead>
<tbody>
<tr>
<td>State</td>
<td>void</td>
<td>Tango::DevState</td>
</tr>
<tr>
<td>Status</td>
<td>void</td>
<td>Tango::DevString</td>
</tr>
<tr>
<td>Init</td>
<td>void</td>
<td>void</td>
</tr>
<tr>
<td>DevRestart</td>
<td>Tango::DevString</td>
<td>void</td>
</tr>
<tr>
<td>RestartServer</td>
<td>void</td>
<td>void</td>
</tr>
<tr>
<td>QueryClass</td>
<td>void</td>
<td>Tango::DevVarStringArray</td>
</tr>
<tr>
<td>QueryDevice</td>
<td>void</td>
<td>Tango::DevVarStringArray</td>
</tr>
<tr>
<td>Kill</td>
<td>void</td>
<td>void</td>
</tr>
<tr>
<td>QueryWizardClassProperty</td>
<td>Tango::DevString</td>
<td>Tango::DevVarStringArray</td>
</tr>
<tr>
<td>QueryWizardDevProperty</td>
<td>Tango::DevString</td>
<td>Tango::DevVarStringArray</td>
</tr>
<tr>
<td>StartPolling</td>
<td>void</td>
<td>void</td>
</tr>
<tr>
<td>StopPolling</td>
<td>void</td>
<td>void</td>
</tr>
<tr>
<td>AddObjPolling</td>
<td>Tango::DevVarLongStringArray</td>
<td>void</td>
</tr>
<tr>
<td>RemObjPolling</td>
<td>Tango::DevVarStringArray</td>
<td>void</td>
</tr>
<tr>
<td>UpdObjPollingPeriod</td>
<td>Tango::DevVarLongStringArray</td>
<td>void</td>
</tr>
<tr>
<td>PolledDevice</td>
<td>void</td>
<td>Tango::DevVarStringArray</td>
</tr>
<tr>
<td>DevPollStatus</td>
<td>Tango::DevString</td>
<td>Tango::DevVarStringArray</td>
</tr>
<tr>
<td>EventSubscriptionChange</td>
<td>Tango::DevVarStringArray</td>
<td>void</td>
</tr>
<tr>
<td>AddLoggingTarget</td>
<td>Tango::DevVarStringArray</td>
<td>void</td>
</tr>
<tr>
<td>RemoveLoggingTarget</td>
<td>Tango::DevVarStringArray</td>
<td>void</td>
</tr>
<tr>
<td>GetLoggingTarget</td>
<td>Tango::DevString</td>
<td>Tango::DevVarStringArray</td>
</tr>
<tr>
<td>GetLoggingLevel</td>
<td>Tango::DevVarStringArray</td>
<td>Tango::DevVarLongStringArray</td>
</tr>
<tr>
<td>SetLoggingLevel</td>
<td>Tango::DevVarLongStringArray</td>
<td>void</td>
</tr>
<tr>
<td>StopLogging</td>
<td>void</td>
<td>void</td>
</tr>
<tr>
<td>StartLogging</td>
<td>void</td>
<td>void</td>
</tr>
</tbody>
</table>

The device description field is set to “A device server device”. Device server started with the `-f` command line option also supports a command called QueryEventChannelIOR. This command is used internally by the Tango kernel classes when the event system is used with device server using database on file.
A.6.1 The State command
This device state is always set to ON

A.6.2 The Status command
This device status is always set to “The device is ON” followed by a new line character and a string describing polling thread status. This string is either “The polling is OFF” or “The polling is ON” according to polling state.

A.6.3 The DevRestart command
The DevRestart command restarts a device. The name of the device to be re-started is the command input parameter. The command destroys the device by calling its destructor and re-create it from its constructor.

A.6.4 The RestartServer command
The DevRestartServer command restarts all the device pattern(s) embedded in the device server process. Therefore, all the devices implemented in the server process are destroyed and re-built\(^1\).

The network connection between client(s) and device(s) implemented in the device server process is destroyed and re-built.

Executing this command allows a complete restart of the device server without stopping the process.

A.6.5 The QueryClass command
This command returns to the client the list of Tango device class(es) embedded in the device server. It returns only class(es) implemented by the device server programmer. The DServer device class name (implemented by the TANGO core software) is not returned by this command.

A.6.6 The QueryDevice command
This command returns to the client the list of device name for all the device(s) implemented in the device server process. Each device name is returned using the following syntax:

\[
\text{<class name>::<device name>}
\]

The name of the DServer class device is not returned by this command.

A.6.7 The Kill command
This command stops the device server process. In order that the client receives a last answer from the server, this command starts a thread which will after a short delay, kills the device server process.

A.6.8 The QueryWizardClassProperty command
This command returns the list of property(ies) defined for a class stored in the device server process property wizard. For each property, its name, a description and a default value is returned.

A.6.9 The QueryWizardDevProperty command
This command returns the list of property(ies) defined for a device stored in the device server process property wizard. For each property, its name, a description and a default value is returned.

\(^1\)Their black-box is also destroyed and re-built
A.6.10  The StartPolling command
This command starts the polling thread

A.6.11  The StopPolling command
This command stops the polling thread

A.6.12  The AddObjPolling command
This command adds a new object in the list of object(s) to be polled. The command input parameters are embedded within a Tango::DevVarLongStringArray data type with one long data and three strings. The input parameters are:

<table>
<thead>
<tr>
<th>Command parameter</th>
<th>Parameter meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>svalue[0]</td>
<td>Device name</td>
</tr>
<tr>
<td>svalue[1]</td>
<td>Object type (&quot;command&quot; or &quot;attribute&quot;)</td>
</tr>
<tr>
<td>svalue[2]</td>
<td>Object name</td>
</tr>
<tr>
<td>lvalue[0]</td>
<td>polling period in mS</td>
</tr>
</tbody>
</table>

The object type string is case independent. The object name string (command name or attribute name) is case dependent. This command does not start polling if it is stopped.

A.6.13  The RemObjPolling command
This command removes an object of the list of polled objects. The command input data type is a Tango::DevVarStringArray with three strings. These strings meaning are:

<table>
<thead>
<tr>
<th>String</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>string[0]</td>
<td>Device name</td>
</tr>
<tr>
<td>string[1]</td>
<td>Object type (&quot;command&quot; or &quot;attribute&quot;)</td>
</tr>
<tr>
<td>string[2]</td>
<td>Object name</td>
</tr>
</tbody>
</table>

The object type string is case independent. The object name string (command name or attribute name) is case dependent

A.6.14  The UpdObjPollingPeriod command
This command changes the polling period for a specified object. The command input parameters are embedded within a Tango::DevVarLongStringArray data type with one long data and three strings. The input parameters are:

<table>
<thead>
<tr>
<th>Command parameter</th>
<th>Parameter meaning</th>
</tr>
</thead>
</table>

A.6.15 The PolledDevice command

This command returns the name of device which are polled. Each string in the Tango::DevVarStringArray returned by the command is a device name which has at least one command or attribute polled. The list is alphabetically sorted.

A.6.16 The DevPollStatus command

This command returns a polling status for a specific device. The input parameter is a device name. Each string in the Tango::DevVarStringArray returned by the command is the polling status for each polled device objects (command or attribute). For each polled objects, the polling status is:

- The object name
- The object polling period (in mS)
- The object polling buffer depth
- The time needed (in mS) for the last command execution or attribute reading
- The time since data in the ring buffer has not been updated. This allows a check of the polling thread
- The delta time between the last records in the ring buffer. This allows checking that the polling period is respected by the polling thread.
- The exception parameters in case of the last command execution or the last attribute reading failed.

A new line character is inserted between each piece of information.

A.6.17 The EventSubscriptionChange command (C++ server only)

This command is used as a piece of the "heartbeat" system between an event client and the device server generating the event. There is no reason to generate events if there is no client which has subscribed to it. It is used by the DeviceProxy::subscribe_event() method and the event thread on the client side to inform the server to keep on generating events for the attribute in question. It reloads the subscription timer with the current time. Events are not generated when there are no clients subscribed within the last 10 minutes. The input parameters are:

<table>
<thead>
<tr>
<th>Command parameter</th>
<th>Parameter meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>argin[0]</td>
<td>Device name</td>
</tr>
<tr>
<td>argin[1]</td>
<td>Attribute name</td>
</tr>
<tr>
<td>argin[2]</td>
<td>action (&quot;subscribe&quot; or &quot;unsubscribe&quot;)</td>
</tr>
<tr>
<td>argin[3]</td>
<td>event name (&quot;change&quot;, &quot;quality&quot;, &quot;periodic&quot;, &quot;archive&quot;)</td>
</tr>
</tbody>
</table>
A.6.18 The AddLoggingTarget command

This command adds one (or more) logging target(s) to the specified device(s). The command input parameter is an array of string logically composed of `{device_name, target_type::target_name}` groups where the elements have the following semantic:

- **device_name** is the name of the device which logging behavior is to be controlled. The wildcard "*" is supported to apply the modification to all devices encapsulated within the device server (e.g. to ask all devices to log to the same device target).

- **target_type::target_name**: target-type is one of the supported target types and target-name, the name of the target. Supported target types are: `console`, `file` and `device`. For a device target, target-name must contain the name of a log consumer device (as defined in A.7). For a file target, target-name is the full path to the file to log to. If omitted the device's name is used to build the file name (domain_family_member.log). Finally, target-name is ignored in the case of a console target and can be omitted.

A.6.19 The RemoveLoggingTarget command

Remove one (or more) logging target(s) from the specified device(s). The command input parameter is an array of string logically composed of `{device_name, target_type::target_name}` groups where the elements have the following semantic:

- **device_name**: the name of the device which logging behavior is to be controlled. The wildcard "*" is supported to apply the modification to all devices encapsulated within the device server (e.g. to ask all devices to stop logging to a given device target).

- **target_type::target_name**: target-type is one of the supported target types and target-name, the name of the target. Supported target types are: `console`, `file` and `device`. For a device target, target-name must contain the name of a log consumer device (as defined in A.7). For a file target, target-name is the full path to the file to log to. If omitted the device's name is used to build the file name (domain_family_member.log). Finally, target-name is ignored in the case of a console target and can be omitted.

The wildcard "*" is supported for target-name. For instance, `RemoveLoggingTarget ([$*, "device::*"])` removes all the device targets from all the devices running in the device server.

A.6.20 The GetLoggingTarget command

Returns the current target list of the specified device. The command parameter device_name is the name of the device which logging target list is requested. The list is returned as a Dev-VarStringArray containing target_type::target_name elements.

A.6.21 The GetLoggingLevel command

Returns the logging level of the specified devices. The command input parameter device_list contains the names of the devices which logging target list is requested. The wildcard "*" is supported to get the logging level of all the devices running within the server. The string part of the result contains the name of the devices and its long part contains the levels. Obviously, result.value[i] is the current logging level of the device named result.name[i].
A.6.22 The SetLoggingLevel command

Changes the logging level of the specified devices. The string part of the command input parameter contains the device names while its long part contains the logging levels. The set of possible values for levels is: 0=OFF, 1=FATAL, 2=ERROR, 3=WARNING, 4=INFO, 5=DEBUG.

The wildcard "*" is supported to assign all devices the same logging level. For instance, SetLoggingLevel (["**"] [3]) set the logging level of all the devices running within the server to WARNING.

A.6.23 The StopLogging command

For all the devices running within the server, StopLogging saves their current logging level and set their logging level to OFF.

A.6.24 The StartLogging command

For each device running within the server, StartLogging restores their logging level to the value stored during a previous StopLogging call.

A.7 Tango log consumer

A.7.1 The available Log Consumer

One implementation of a log consumer associated to a graphical user interface is available within Tango. It is a standalone java application called LogViewer based on the publicly available chainsaw application from the log4j package. It supports two way of running which are:

- The static mode: In this mode, LogViewer is started with a parameter which is the name of the log consumer device implemented by the application. All messages sent by devices with a logging target type set to device and with a logging target name set to the same device name than the device name passed as application parameter will be displayed (if the logging level allows it).

- The dynamic mode: In this mode, the name of the log consumer device implemented by the application is build at application startup and is dynamic. The user with the help of the graphical interface chooses device(s) for which he want to see log messages.

A.7.2 The Log Consumer interface

A Tango Log Consumer device is nothing but a tango device supporting the following tango command:

```java
void log (Tango::DevVarStringArray details)
```

where details is an array of string carrying the log details. Its structure is:

- details[0] : the timestamp in millisecond since epoch (01.01.1970)
- details[1] : the log level
- details[2] : the log source (i.e. device name)
- details[4] : the log NDC (contextual info) - Not used but reserved
- details[5] : the thread identifier (i.e. the thread from which the log request comes from)

These log details can easily be extended. Any tango device supporting this command can act as a device target for other devices.
A.8 Control system specific

It is possible to define a few control system parameters. By control system, we mean for each set of computers having the same database device server (the same TANGO_HOST environment variable).

A.8.1 The device class documentation default value

Each control system may have its own default device class documentation value. This is defined via a class property. The property name is

```
Default->doc_url
```

It’s retrieved if the device class itself does not define any doc_url property. If the Default->doc_url property is also not defined, a hard-coded default value is provided.

A.9 C++ specific

A.9.1 The Tango master include file (tango.h)

Tango has a master include file called

```
tango.h
```

This master include file includes the following files:

- C++ language include file: `typeid`
- Tango configuration include file: `tango_config.h`
- CORBA include file: `idl/tango.h`
- Some network include files for WIN32: `winsock2.h` and `mswsock.h`
- C++ streams include file:
  - `iostream`, `sstream` and `fstream` for Windows NT and Solaris with its native compiler
  - `iostream.h`, `sstream.h`, `fstream.h` and `sstream` for Linux and Solaris with gcc
- Some standard C++ library include files: `string` and `vector`
- The main include file generated by the CORBA IDL compiler: `idl/tango.h`
- The Tango database and device API include files: `dbapi.h` and `devapi.h`
- A list of other Tango include files: `tango_const.h`, `utils.h`, `device.h`, `command.h`, `except.h`, `seqvec.h`, `device_2.h`, `log4tango.h`, `attrmanip.h` and `dserver.h`

A.9.2 Tango specific types

Operating system free type

Some data type used in the TANGO core software are not the same under UNIX like operating system and Windows NT. In order to have less "#ifdef" in the source code, some Tango types have been defined. They are described in the following table.

<table>
<thead>
<tr>
<th>Type name</th>
<th>Unix like</th>
<th>Windows NT</th>
</tr>
</thead>
</table>
These types are defined in the tango_config.h file

### A.9.2.1 Template command model related type

As explained in 8.4.8, command created with the template command model uses static casting. Many type definition have been written for these casting.

<table>
<thead>
<tr>
<th>Class name</th>
<th>Command allowed method (if any)</th>
<th>Command execute method</th>
</tr>
</thead>
<tbody>
<tr>
<td>TemplCommand</td>
<td>Tango::StateMethodPtr</td>
<td>Tango::CmdMethPtr</td>
</tr>
<tr>
<td>TemplCommandIn</td>
<td>Tango::StateMethodPtr</td>
<td>Tango::CmdMethPtr xxx</td>
</tr>
<tr>
<td>TemplCommandOut</td>
<td>Tango::StateMethodPtr</td>
<td>Tango::xxx_CmdMethPtr</td>
</tr>
<tr>
<td>TemplCommandInOut</td>
<td>Tango::StateMethodPtr</td>
<td>Tango::xxx_CmdMethPtr yyy</td>
</tr>
</tbody>
</table>

The Tango::StateMethPtr is a pointer to a method of the DeviceImpl class which returns a boolean and has one parameter which is a reference to a const CORBA::Any object.

The Tango::CmdMethPtr is a pointer to a method of the DeviceImpl class which returns nothing and needs nothing as parameter.

The Tango::CmdMethPtr xxx is a pointer to a method of the DeviceImpl class which returns nothing and has one parameter. xxx must be set according to the method parameter type as described in the next table.

<table>
<thead>
<tr>
<th>Tango type</th>
<th>short cut (xxx)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Tango::DevBoolean</td>
<td>Bo</td>
</tr>
<tr>
<td>Tango::DevShort</td>
<td>Sh</td>
</tr>
<tr>
<td>Tango::DevLong</td>
<td>Lg</td>
</tr>
<tr>
<td>Tango::DevFloat</td>
<td>Fl</td>
</tr>
<tr>
<td>Tango::DevDouble</td>
<td>Db</td>
</tr>
<tr>
<td>Tango::DevUshort</td>
<td>US</td>
</tr>
<tr>
<td>Tango::DevULong</td>
<td>UL</td>
</tr>
<tr>
<td>Tango::DevString</td>
<td>Str</td>
</tr>
<tr>
<td>Tango::DevVarCharArray</td>
<td>ChA</td>
</tr>
<tr>
<td>Tango::DevVarShortArray</td>
<td>ShA</td>
</tr>
<tr>
<td>Tango::DevVarLongArray</td>
<td>LgA</td>
</tr>
<tr>
<td>Tango::DevVarFloatArray</td>
<td>FlA</td>
</tr>
<tr>
<td>Tango::DevVarDoubleArray</td>
<td>DbA</td>
</tr>
<tr>
<td>Tango::DevVarUShortArray</td>
<td>USA</td>
</tr>
<tr>
<td>Tango::DevVarULongArray</td>
<td>ULA</td>
</tr>
<tr>
<td>Tango::DevVarStringArray</td>
<td>StrA</td>
</tr>
<tr>
<td>Tango::DevVarLongStringArray</td>
<td>LSA</td>
</tr>
</tbody>
</table>
A.9.3 Tango device state code

The Tango::DevState type is a C++ enumeration starting at 0. The code associated with each state is defined in the following table.

<table>
<thead>
<tr>
<th>State name</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Tango::ON</td>
<td>0</td>
</tr>
<tr>
<td>Tango::OFF</td>
<td>1</td>
</tr>
<tr>
<td>Tango::CLOSE</td>
<td>2</td>
</tr>
<tr>
<td>Tango::OPEN</td>
<td>3</td>
</tr>
<tr>
<td>Tango::INSERT</td>
<td>4</td>
</tr>
<tr>
<td>Tango::EXTRACT</td>
<td>5</td>
</tr>
<tr>
<td>Tango::MOVING</td>
<td>6</td>
</tr>
<tr>
<td>Tango::STANDBY</td>
<td>7</td>
</tr>
<tr>
<td>Tango::FAULT</td>
<td>8</td>
</tr>
<tr>
<td>Tango::INIT</td>
<td>9</td>
</tr>
<tr>
<td>Tango::RUNNING</td>
<td>10</td>
</tr>
<tr>
<td>Tango::ALARM</td>
<td>11</td>
</tr>
<tr>
<td>Tango::DISABLE</td>
<td>12</td>
</tr>
<tr>
<td>Tango::UNKNOWN</td>
<td>13</td>
</tr>
</tbody>
</table>

A strings array called Tango::DevStateName can be used to get the device state as a string. Use the Tango device state code as index into the array to get the correct string.

A.9.4 Tango data type

A “define” has been created for each Tango data type. This is summarized in the following table.
For command which do not take input parameter, the type code 
Tango::DEV_VOID (value = 0) has been defined.

A string array called Tango::CmdArgType_Name can be used to get the data type as a string. Use the Tango data type code as index into the array to get the correct string.

### A.9.5 Tango command display level

Like attribute, Tango command has a display level. The Tango::DispLevel type is a C++ enumeration starting at 0. The code associated with each command display level is already described in page 372.

As for attribute, this parameter allows a graphical application to support two types of operation:

- An operator mode for day to day operation
- An expert mode when tuning is necessary

According to this parameter, a graphical application knows if the command is for the operator mode or for the expert mode.

### A.10 Java specific

#### A.10.1 Packages

All the Tango core classes are bundled in the a Java package called fr.esrf.TangoDs. All the classes generated by the IDL compiler are bundled in a Java package called fr.esrf.Tango.
All the Tango Java API classes are bundled in Java packages called fr.esrf.TangoApi and
fr.esrf.TangoApi.Group. All the CORBA related classes are stored in a package called org.omg.CORBA.
These package Tango, TangoDs, TangoApi, Group and CORBA are stored in the same jar file
called TangORB.jar.

A.11 Device server process option and environment variable

A.11.1 Classical device server

The synopsis of a device server process is

\[ \text{ds\_name instance\_name [OPTIONS]} \]

The supported options are:

- **-h, -? -help**
  Print the device server synopsis and a list of instance name defined in the database for this
device server. An instance name in not mandatory in the command line to use this option

- **-v[trace level]**
  Set the verbose level. If no trace level is given, a default value of 4 is used

- **-file=<file name path>**
  Start a device server using an ASCII file instead of the Tango database.

- **-nodb**
  Start a device server without using the database.

- **-dlist <device name list>**
  Give the device name list. This option is supported only with the -nodb option.

- **ORB options (started with -ORBxxx)**
  Options directly passed to the underlying ORB. Should be rarely used except the -ORBendPoint
  option for device server not using the database

A.11.2 Device server process as Windows service

When used as a Windows service, a Tango device server supports several new options. These
options are:

- **-i**
  Install the service

- **-s**
  Install the service and choose the automatic startup mode

- **-u**
  Un-install the service

- **-dbg**
  Run in console mode to debug service. The service must have been installed prior to use it.

Note that these options must be used after the device server instance name.

A.11.3 Environment variables

Two environment variables can be used to tune a Tango control system. TANGO_HOST is the
most important one but on top it, some Tango features like Tango logging service can be tuned
using environment variable.
A.11.3.1 TANGO_HOST

This environment variable is the anchor of the system. It specifies where the Tango database server is running. Most of the time, its syntax is

\[
\text{TANGO\_HOST} = <\text{host}>:<\text{port}>
\]

host is the name of the computer where the database server is running and port is the port number on which it is listening. If you want to have a Tango control system which has several database servers (but only one database) in order to survive a database server crashes, use the following syntax

\[
\text{TANGO\_HOST} = <\text{host}\_1>:<\text{port}\_1>,<\text{host}\_2>:<\text{port}\_2>,<\text{host}\_3>:<\text{port}\_3>
\]

Obviously, host\_1 is the name of the computer where the first database server is running, port\_1 is the port number on which this server is listening. host\_2 is the name of the computer where the second database server is running and port\_2 is its port number. All access to database will automatically switch from one server to another one in the list if the one which was used has died.

A.11.3.2 Tango Logging Service (TANGO_LOG_PATH)

The TANGO\_LOG\_PATH environment variable can be used to specify the log files location. If not set, it defaults to /tmp/tango under Unix and c:\tango under Windows. For a given device-server, the files are actually saved into $\text{TANGO\_LOG\_PATH}/\{\text{server\_name}\}/\{\text{server\_instance\_name}\}.

This means that all the devices running within the same process log into the same directory.

A.11.3.3 The database server (MYSQL_USER and MYSQL_PASSWORD)

The Tango database server needs to connect to the MySQL database. It uses two environment variables called MYSQL\_USER and MYSQL\_PASSWORD to know which user/password it must uses to access the database. If these environment variables are not defined, the database server will connect using the "root" login.
Appendix B

The TANGO IDL file: Module Tango

The fundamental idea of a device as a network object which has methods and data has been retained for TANGO. In TANGO objects are real C++/Java objects which can be instantiated and accessed via their methods and data by the client as if they were local objects. This interface is defined in CORBA IDL. The fundamental interface is Device. All TANGO control objects will be of this type i.e. they will implement and offer the Device interface. Some wrapper classes group in an API will hide the calls to the Device interface from the client so that the client will only see the wrapper classes. All CORBA details will be hidden from the client as far as possible.

typedef sequence<NamedDevError> NamedDevErrorList;

### B.2 Enums

AttrDataFormat
enum AttrDataFormat
{
   SCALAR,
   SPECTRUM,
   IMAGE
};
AttrQuality

enum AttrQuality
{
    ATTR_VALID,
    ATTR_INVALID,
    ATTR_ALARM,
    ATTR_CHANGING,
    ATTR_WARNING
};

AttrWriteType

enum AttrWriteType
{
    READ,
    READ_WITH_WRITE,
    WRITE,
    READ_WRITE
};

DispLevel

enum DispLevel
{
    OPERATOR,
    EXPERT
};

DevSource

enum DevSource
{
    DEV,
    CACHE,
    CACHE_DEV
};

DevState

enum DevState
{
    ON,
    OFF,
    CLOSE,
    OPEN,
    INSERT,
    EXTRACT,
    MOVING,
    STANDBY,
    FAULT,
    INIT,
APPENDIX B. THE TANGO IDL FILE : MODULE TANGO

RUNNING,
ALARM,
DISABLE,
UNKNOWN
}

ErrSeverity

enum ErrSeverity
{
    WARN,
    ERR,
    PANIC
};

B.3 Structs

ArchiveEventProp
struct ArchiveEventProp
{
    string rel_change;
    string abs_change;
    string period;
    DevVarStringArray extensions;
};

AttributeAlarm
struct AttributeAlarm
{
    string min_alarm;
    string max_alarm;
    string min_warning;
    string max_warning;
    string delta_t;
    string delta_val;
    DevVarStringArray extensions;
};

AttributeConfig
struct AttributeConfig
{
    string name;
    AttrWriteType writable;
    AttrDataFormat data_format;
    long data_type;
    long max_dim_x;
    long max_dim_y;
    string description;
    string label;
    string unit;
    string standard_unit;
    string display_unit;
}
string format;
string min_value;
string max_value;
string min_alarm;
string max_alarm;
string writable_attr_name;
        DevVarStringArray extensions;
};

AttributeConfig_2
{
    string name;
    AttrWriteType writable;
    AttrDataFormat data_format;
    long data_type;
    long max_dim_x;
    long max_dim_y;
    string description;
    string label;
    string unit;
    string standard_unit;
    string display_unit;
    string format;
    string min_value;
    string max_value;
    string min_alarm;
    string max_alarm;
    string writable_attr_name;
    DispLevel level;
    DevVarStringArray extensions;
};

AttributeConfig_3
{
    string name;
    AttrWriteType writable;
    AttrDataFormat data_format;
    long data_type;
    long max_dim_x;
    long max_dim_y;
    string description;
    string label;
    string unit;
    string standard_unit;
    string display_unit;
    string format;
    string min_value;
    string max_value;
APPENDIX B. THE TANGO IDL FILE : MODULE TANGO

```idl
string writable_attr_name;
DispLevel level;
AttributeAlarm alarm;
EventProperties event_prop;
DevVarStringArray extensions;
DevVarStringArray sys_extensions;
```

`AttributeDim`

```idl
struct AttributeDim
{
    long dim_x;
    long dim_y;
};
```

`AttributeValue`

```idl
struct AttributeValue
{
    any value;
    AttrQuality quality;
    TimeVal time;
    string name;
    long dim_x;
    long dim_y;
};
```

`AttributeValue_3`

```idl
struct AttributeValue_3
{
    any value;
    AttrQuality quality;
    TimeVal time;
    string name;
    AttributeDim r_dim;
    AttributeDim w_dim;
    DevErrorList err_list;
};
```

`ChangeEventProp`

```idl
struct ChangeEventProp
{
    string rel_change;
    string abs_change;
    DevVarStringArray extensions;
};
```

`DevAttrHistory`
struct DevAttrHistory
{
    boolean attr_failed;
    AttributeValue value;
    DevErrorList errors;
};

DevAttrHistory_3
struct DevAttrHistory_3
{
    boolean attr_failed;
    AttributeValue_3 value;
};

DevCmdHistory
struct DevCmdHistory
{
    TimeVal time;
    boolean cmd_failed;
    any value;
    DevErrorList errors;
};

DevCmdInfo
struct DevCmdInfo
{
    string cmd_name;
    long cmd_tag;
    long in_type;
    long out_type;
    string in_type_desc;
    string out_type_desc;
};

DevCmdInfo_2
struct DevCmdInfo_2
{
    string cmd_name;
    DispLevel level;
    long cmd_tag;
    long in_type;
    long out_type;
    string in_type_desc;
    string out_type_desc;
};

DevError
struct DevError
{
    string reason;
    ErrSeverity severity;
    string desc;
    string origin;
};

DevInfo

struct DevInfo
{
    string dev_class;
    string server_id;
    string server_host;
    long server_version;
    string doc_url;
};

DevInfo_3

struct DevInfo_3
{
    string dev_class;
    string server_id;
    string server_host;
    long server_version;
    string doc_url;
    string dev_type;
};

DevVarDoubleStringArray

struct DevVarDoubleStringArray
{
    DevVarDoubleArray dvalue;
    DevVarStringArray svalue;
};

DevVarLongStringArray

struct DevVarLongStringArray
{
    DevVarLongArray lvalue;
    DevVarStringArray svalue;
};

EventProperties
struct EventProperties
{
    ChangeEventProp ch_event;
    PeriodicEventProp per_event;
    ArchiveEventProp arch_event;
};

NamedDevError
struct NamedDevError
{
    string name;
    long index_in_call;
    DevErrorList err_list;
};

PeriodicEventProp
struct PeriodicEventProp
{
    string period;
    DevVarStringArray extensions;
};

TimeVal
struct TimeVal
{
    long tv_sec;
    long tv_usec;
    long tv_nsec;
};

B.4 Exceptions
DevFailed
exception DevFailed
{
    DevErrorList errors;
};

MultiDevFailed
exception MultiDevFailed
{
    NamedDevErrorList errors;
};
B.5 Interface Tango::Device

The fundamental interface for all TANGO objects. Each Device is a network object which can be accessed locally or via network. The network protocol on the wire will be IIOP. The Device interface implements all the basic functions needed for doing generic synchronous and asynchronous I/O on a device. A Device object has data and actions. Data are represented in the form of Attributes. Actions are represented in the form of Commands. The CORBA Device interface offers attributes and methods to access the attributes and commands. A client will either use these methods directly from C++ or Java or access them via wrapper classes implemented in a API. The Device interface describes only the remote network interface. Implementation features like threads, command security, priority etc. are dealt with in server side of the device server model.

B.5.1 Attributes

adm_name
readonly attribute string adm_name;
adm_name (readonly) - administrator device unique ascii identifier

description
readonly attribute string description;
description (readonly) - general description of device

name
readonly attribute string name;
nname (readonly) - unique ascii identifier

state
readonly attribute DevState state;
state (readonly) - device state

status
readonly attribute string status;
status (readonly) - device state as ascii string

B.5.2 Operations

black_box
DevVarStringArray black_box(in long number)
raises(DevFailed);

read list of last N commands executed by clients

Parameters:
number – of commands to return

Returns:
list of command and clients
APPENDIX B. THE TANGO IDL FILE : MODULE TANGO

command_inout

any command_inout(in string command, in any argin)
raises(DevFailed);

execute a command on a device synchronously with no input parameter and one one output parameter

Parameters:
- command – ascii string e.g. "On"
- argin – command input parameter e.g. float

Returns:
- command result.

command_list_query

DevCmdInfoList command_list_query()
raises(DevFailed);

query device to see what commands it supports

Returns:
- list of commands and their types

command_query

DevCmdInfo command_query(in string command)
raises(DevFailed);

query device to see command argument

Parameters:
- command – name

Returns:
- command and its types

get_attribute_config

AttributeConfigList get_attribute_config(in DevVarStringArray names)
raises(DevFailed);

read the configuration for a variable list of attributes from a device

Parameters:
- name – list of attribute names to read

Returns:
- list of attribute configurations read

info
DevInfo info()
raises(DevFailed);

return general information about object e.g. class, type, ...

Returns:
device info

ping

void ping()
raises(DevFailed);

ping a device to see if it alive

read_attributes

AttributeValueList read_attributes(in DevVarStringArray names)
raises(DevFailed);

read a variable list of attributes from a device

Parameters:
name – list of attribute names to read

Returns:
list of attribute values read

set_attribute_config

void set_attribute_config(in AttributeConfigList new_conf)
raises(DevFailed);

set the configuration for a variable list of attributes from the device

Parameters:
new_conf – list of attribute configuration to be set

write_attributes

void write_attributes(in AttributeValueList values)
raises(DevFailed);

write a variable list of attributes to a device

Parameters:
values – list of attribute values to write
B.6 Interface Tango::Device_2

interface Device_2 inherits from Tango::Device

The updated Tango device interface. It inherits from Tango::Device and therefore supports all attribute/operation defined in the Tango::Device interface. Two CORBA operations have been modified to support more parameters (command_inout_2 and read_attribute_2). Three CORBA operations now return a different data type (command_list_query_2, command_query_2 and get_attribute_config).

B.6.1 Operations

command_inout_2

any command_inout_2(in string command, in any argin, in DevSource source)
raises(DevFailed);

execute a command on a device synchronously with no input parameter and one one output parameter.

Parameters:
command - ascii string e.g. "On"
argin - command input parameter e.g. float
source - data source

Returns:
command result.

command_inout_history_2

DevCmdHistoryList command_inout_history_2(in string command, in long n)
raises(DevFailed);

Get command result history from polling buffer. Obviously, the command must be polled.

Parameters:
command - ascii string e.g. "On"
n - record number

Returns:
list of command result (or exception parameters if the command failed).

command_list_query_2

DevCmdInfoList_2 command_list_query_2()
raises(DevFailed);

query device to see what commands it supports

Returns:
list of commands and their types

command_query_2
DevCmdInfo_2 command_query_2(in string command) raises(DevFailed);

query device to see command argument

Parameters:
command – name

Returns:
command and its types

get_attribute_config_2
AttributeConfigList_2 get_attribute_config_2(in DevVarStringArray names) raises(DevFailed);

read the configuration for a variable list of attributes from a device

Parameters:
nname – list of attribute names to read

Returns:
list of attribute configurations read

read_attributes_2
AttributeValueList read_attributes_2(in DevVarStringArray names, in DevSource source) raises(DevFailed)

read a variable list of attributes from a device

Parameters:
nname – list of attribute names to read

Returns:
list of attribute values read

read_attribute_history_2
DevAttrHistoryList read_attribute_history_2(in string name, in long n) raises(DevFailed)

Get attribute value history from polling buffer. Obviously, the attribute must be polled.

Parameters:
nname – Attribute name to read history
nn – Record number

Returns:
list of attribute value (or exception parameters if the attribute failed).
B.7 Interface Tango::Device_3

interface Device_3 inherits from Tango::Device_2

The updated Tango device interface for Tango release 5. It inherits from Tango::Device_2 and therefore supports all attribute/operation defined in the Tango::Device_2 interface. Six CORBA operations now return a different data type (read_attributes_3, write_attributes_3, read_attribute_history_3, info_3, get_attribute_config_3 and set_attribute_config_3)

B.7.1 Operations

read_attributes_3

AttributeValueList_3 read_attributes_3(in DevVarStringArray names, in DevSource source) raises(DevFailed);

read a variable list of attributes from a device

Parameters:
    names – list of attribute names to read
    source – data source

Returns:
    list of attribute values read

write_attributes_3

void write_attributes_3(in AttributeValueList values) raises(DevFailed, MultiDevFailed);

write a variable list of attributes to a device

Parameters:
    values – list of attribute values to write

read_attribute_history_3

DevAttrHistoryList_3 read_attribute_history_3(in string name, in long n) raises(DevFailed)

Get attribute value history from polling buffer. Obviously, the attribute must be polled.

Parameters:
    name – Attribute name to read history
    n – Record number

Returns:
    list of attribute value (or exception parameters if the attribute failed).

info_3

DevInfo_3 info() raises(DevFailed);

return general information about object e.g. class, type, ...
Returns:
device info

get_attribute_config_3

AttributeConfigList_3 get_attribute_config_3(in DevVarStringArray names) raises(DevFailed); read the configuration for a variable list of attributes from a device

Parameters:
name – list of attribute names to read

Returns:
list of attribute configurations read

set_attribute_config_3

void set_attribute_config_3(in AttributeConfigList_3 new_conf) raises(DevFailed); set the configuration for a variable list of attributes from the device

Parameters:
new_conf – list of attribute configuration to be set
Appendix C

Tango object naming (device, attribute and property)

C.1 Device name

A Tango device name is a three fields name. The field separator is the / character. The first field is named domain, the second field is named family and the last field is named member. A Tango device name looks like

\[ \text{domain/family/member} \]

It is a hierarchical notation. The member specifies which element within a family. The family specifies which kind of equipment within a domain. The domain groups devices related to which part of the accelerator/experiment they belongs to. At ESRF, some of the machine control system domain name are SR for the storage ring, TL1 for the transfer line 1 or SY for the synchrotron booster. For example, ID11 is the domain name for all devices belonging to the experiment behind insertion device 11. Here are some examples of Tango device name used at the ESRF:

- \text{sr/d-ct/1} : The current transformer. The domain part is sr for storage ring. The family part is d-ct for diagnostic/current transformer and the member part is 1

- \text{fe/v-pen/id11-1} : A Penning gauge. The domain part is fe for front-end. The family part is v-pen for vacuum/penning and the member name is id11-1 to specify that this is the first gauge on the front-end part after the insertion device 11

C.2 Full object name

The device name as described above is not enough to cover all Tango usage like device server without database or device access for multi control system. With the naming schema, we must also be able to name attribute and property. Therefore, the full naming schema is

\[ \text{/protocol://host:port/device name/attribute/-property/#dbase=xx} \]

The protocol, host, port, attribute, property and dbase fields are optional. The meaning of these fields are:

- protocol : Specifies which protocol is used (Tango or Taco). Tango is the default

- dbase=xx : The supported value for xx is yes and no. This field is used to specify that the device is a device served by a device server started with or without database usage. The default value is \text{dbase=yes}
APPENDIX C. TANGO OBJECT NAMING (DEVICE, ATTRIBUTE AND PROPERTY) 408

host:port  : This field has different meaning according to the dbase value. If dbase=yes (the default), the host is the host where the control system database server is running and port is the database server port. It has a higher priority than the value defined by the TANGO_HOST environment variable. If dbase=no, host is the host name where the device server process serving the device is running and port is the device server process port.

attribute : The attribute name

property : The property name

The host:port and dbase=xx fields are necessary only when creating the DeviceProxy object used to remotely access the device. The -> characters are used to specify a property name.

C.2.1 Some examples

C.2.1.1 Full device name examples

- **gizmo:20000/*r/*d-ct/1** : Device sr/d-ct/1 running in a specified control system with the database server running on a host called gizmo and using the port number 20000. The TANGO_HOST environment variable will not be used.

- **tango://freak:2345/*id11/*rv/1/dbase=no** : Device served by a device server started without database. The server is running on a host called freak and use port number 2345. //freak:2345/*id11/*rv/1/dbase=no is also possible for the same device.

- **Taco://sy/*ps-ki/1** : Taco device sy/ps-ki/1

C.2.1.2 Attribute name examples

- **id11/mot/1/Position** : Attribute position for device id11/mot/1

- **sr/*d-ct/1/Lifetime** : Attribute lifetime for Tango device sr/*d-ct/1

C.2.1.3 Attribute property name

- **id11/*rv/1/temp->label** : Property label for attribute temp for device id11/*rv/1.

- **sr/*d-ct/1/Lifetime->unit** : The unit property for the Lifetime attribute of the sr/*d-ct/1 device

C.2.1.4 Device property name

- **sr/*d-ct/1->address** : the address property for device sr/*d-ct/1

C.2.1.5 Class property name

- **Starter->doc_url** : The doc_url property for a class called Starter

C.3 Device and attribute name alias

Within Tango, each device or attribute can have an alias name defined in the database. Every time a device or an attribute name is requested by the API's, it is possible to use the alias. The alias is simply an open string stored in the database. The rule of the alias is to give device or attribute name a name more natural from the physicist point of view. Let's imagine that for experiment, the sample position is described by angles called teta and psi in physics book. It is more natural for physicist when they move the motor related to sample position to use teta and psi rather
device name like `idx/mot/1` or `idx/mot/2`. An attribute alias is a synonym for the four fields used to name an attribute. For instance, the attribute `Current` of a power-supply device called `sr/ps/dipole` could have an alias `DipoleCurrent`. This alias can be used when creating an instance of a `AttributeProxy` class instead of the full attribute name which is `sr/ps/dipole/Current`. Device alias name are uniq within a Tango control system. Attribute alias name are also uniq within a Tango control system.

C.4 Reserved words and characters, limitations

From the naming schema described above, the reserved characters are `;#./` and the reserved string is `:->`. On top of that, the `dbt_update` tool (tool to fulfill database from the content of a file) reserved the `device` word.

The device name, its domain, member and family fields and its alias are stored in the Tango database. The default maximum size for these items are:

<table>
<thead>
<tr>
<th>Item</th>
<th>max length</th>
</tr>
</thead>
<tbody>
<tr>
<td>device name</td>
<td>255</td>
</tr>
<tr>
<td>domain field</td>
<td>85</td>
</tr>
<tr>
<td>family field</td>
<td>85</td>
</tr>
<tr>
<td>member field</td>
<td>85</td>
</tr>
<tr>
<td>device alias name</td>
<td>255</td>
</tr>
</tbody>
</table>

The device name, the command name, the attribute name, the property name, the device alias name and the device server name are **case insensitive**.
Appendix D

Starting a Tango control system

D.1 Without database
When used without database, there is no additional process to start. Simply starts device server using the -nodb option (and eventually the -dlist option) on specific port. See 9.7 to find informations on how to start/write Tango device server not using the database.

D.2 With database
Starting the Tango control system simply means starting its database device server on a well defined host using a well defined port. Use the host name and the port number to build the TANGO_HOST environment variable. See 8.6.2 to find how starting a device server on a specific host. Obviously, the underlying database software (MySQL) must be started before the Tango database device server. The Tango database server connects to MySQL using a default logging name set to "root". You can change this behaviour with the MYSQL_USER and MYSQL_PASSWORD environment variables. Define them before starting the database server.

If you are using the Tango administration graphical tool called Astor, you also need to start a specific Tango device server called Starter on each host where Tango device server(s) are running. See [19] for Astor documentation. This starter device server is able to start even before the Tango database device server is started. In this case, it will enter a loop in which it periodically tries to access the Tango database device. The loop exits and the server starts only if the database device access succeed.

D.3 With database and event
On top of what is described in the previous chapter, using event means using CORBA Notification service. Start one Notification Service daemon on each host where device server(s) used via events are running. The Notification Service daemon event channel factory IOR has to be registered in the Tango database. This is done with thenotif2db command. Example of starting and registering a Notification Service daemon on a UNIX like operating system

1  notifd -n &
2 notifd2db
The Notification Service daemon is started at line 1. Its "-n" option is used to disable the use of the CORBA Naming Service for registering the default event channel factory. The registration of the Notification Service daemon in the Tango database is done at line 2.

It differs on a Windows computer

```
1 notifd -n -DFactoryIORFileName=C:\Temp\evfact.ior &
2 notifd2db C:\Temp\evfact.ior
```

### D.4 With file used as database

When used with database on file, there is no additional process to start. Simply starts device server using the -file option specifying file name port. See 9.6 to find informations on how to start Tango device server using database on file.

### D.5 With file used as database and event

Using event means using CORBA Notification service. Start one Notification Service daemon on the host where device server(s) using events are running. The Notification Service daemon event channel factory IOR has to be registered in the file(s) use as database. This is done with the `notifd2db` command. Example of starting and registering a Notification Service daemon on a UNIX like operating system

```
1 notifd -n &
2 notifd2db -o /var/myfile.res
```

The Notification Service daemon is started at line 1. Its "-n" option is used to disable the use of the CORBA Naming Service for registering the default event channel factory. The registration of the Notification Service daemon in the file used as database is done at line 2 with its -o command line option.

It differs on a Windows computer because the name of the file used by the CORBA notification service to store its channel factory IOR must be specified using its -D command line option. This file name has also to be passed to the notifd2db command.

```
1 notifd -n -DFactoryIORFileName=C:\Temp\evfact.ior &
2 notifd2db C:\Temp\evfact.ior -o C:\Temp\myfile.res
```
Appendix E

The notifd2db utility

E.1 The notifd2db utility usage

The notifd2db utility is used to pass to Tango the necessary information for the Tango servers or clients to build connection with the CORBA notification service. Its usage is:

```
notifd2db [notifd2db_IOR_file] [host] [-o Device_server_database_file_name] [-h]
```

The [notifd2db_IOR_file] parameter is used to specify the file name used by the notification service to store its main IOR. This parameter is not mandatory. Its default value is /tmp/rdfact.ior. The [host] parameter is used to specify on which host the notification service should be exported. The default value is the host on which the command is run. The [-o Device_server_database_file_name] is used in case of event and device server started with the file as database (the -file device server command line option). The file name used here must be the file name used by the device server in its -file option. The [-h] option is just to display an help message. Notifd2db utility usage example:

```
notifd2db
```
to register notification service on the current host using the default notification service IOR file name.

```
notifd C:\Temp\nd.ior
```
to register a notification service with IOR file named C:\Temp\nd.ior.

```
notifd -o /var/my_ds_file.res
```
to register notification service in the /var/my_ds_file.res file used by a device server started with the device server -file command line option.
