## Use of Database in Automatic Control & Remote Monitoring

Laurent Lardon  
Jean-Philippe Steyer  
Laboratoire de Biotechnologie  
de l'Environnement  
INRA  
Narbonne

BioXHIT workshop, Grenoble, 4-5 May 2004

- **Supervision and Information System**
- **Database : main ideas and implementation**
- **Integration of distributed applications**
- **Practical Realisations (the TELEMAC project)**
  - ✦ **web interfaces**
  - ✦ **traceability**

# The Anaerobic Digestion Process

**Influent** : Distillery Wastewater (CODs  $\approx$  40 g/l)

**Reactor** : Fixed Bed Reactor

- Height : 3.5 m
- Diameter : 0.6 m,
- Total Volume : 982 liters

# The Anaerobic Digestion Process

*In 1997*

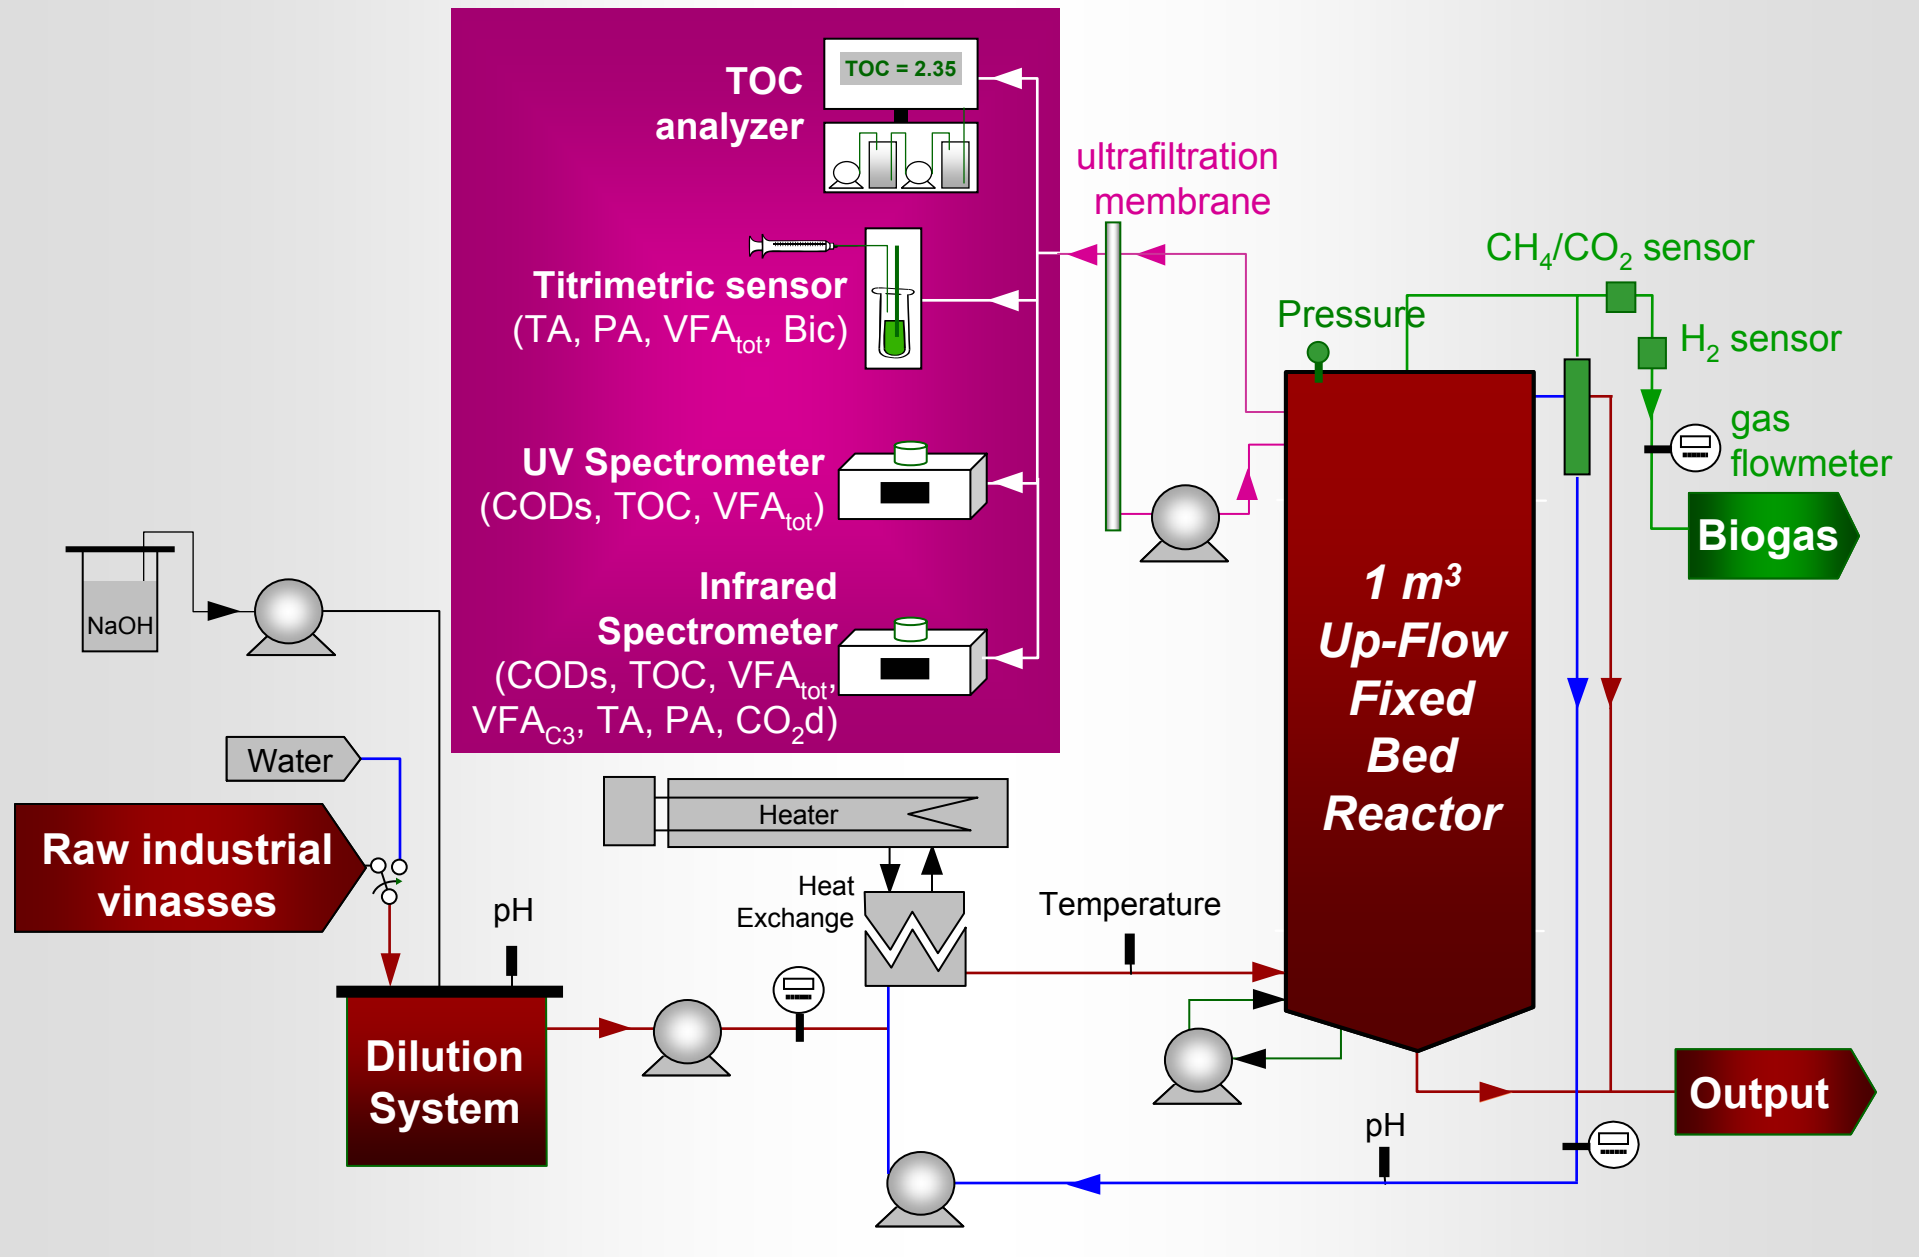

*Since 1999*

# Schematic layout of the plant

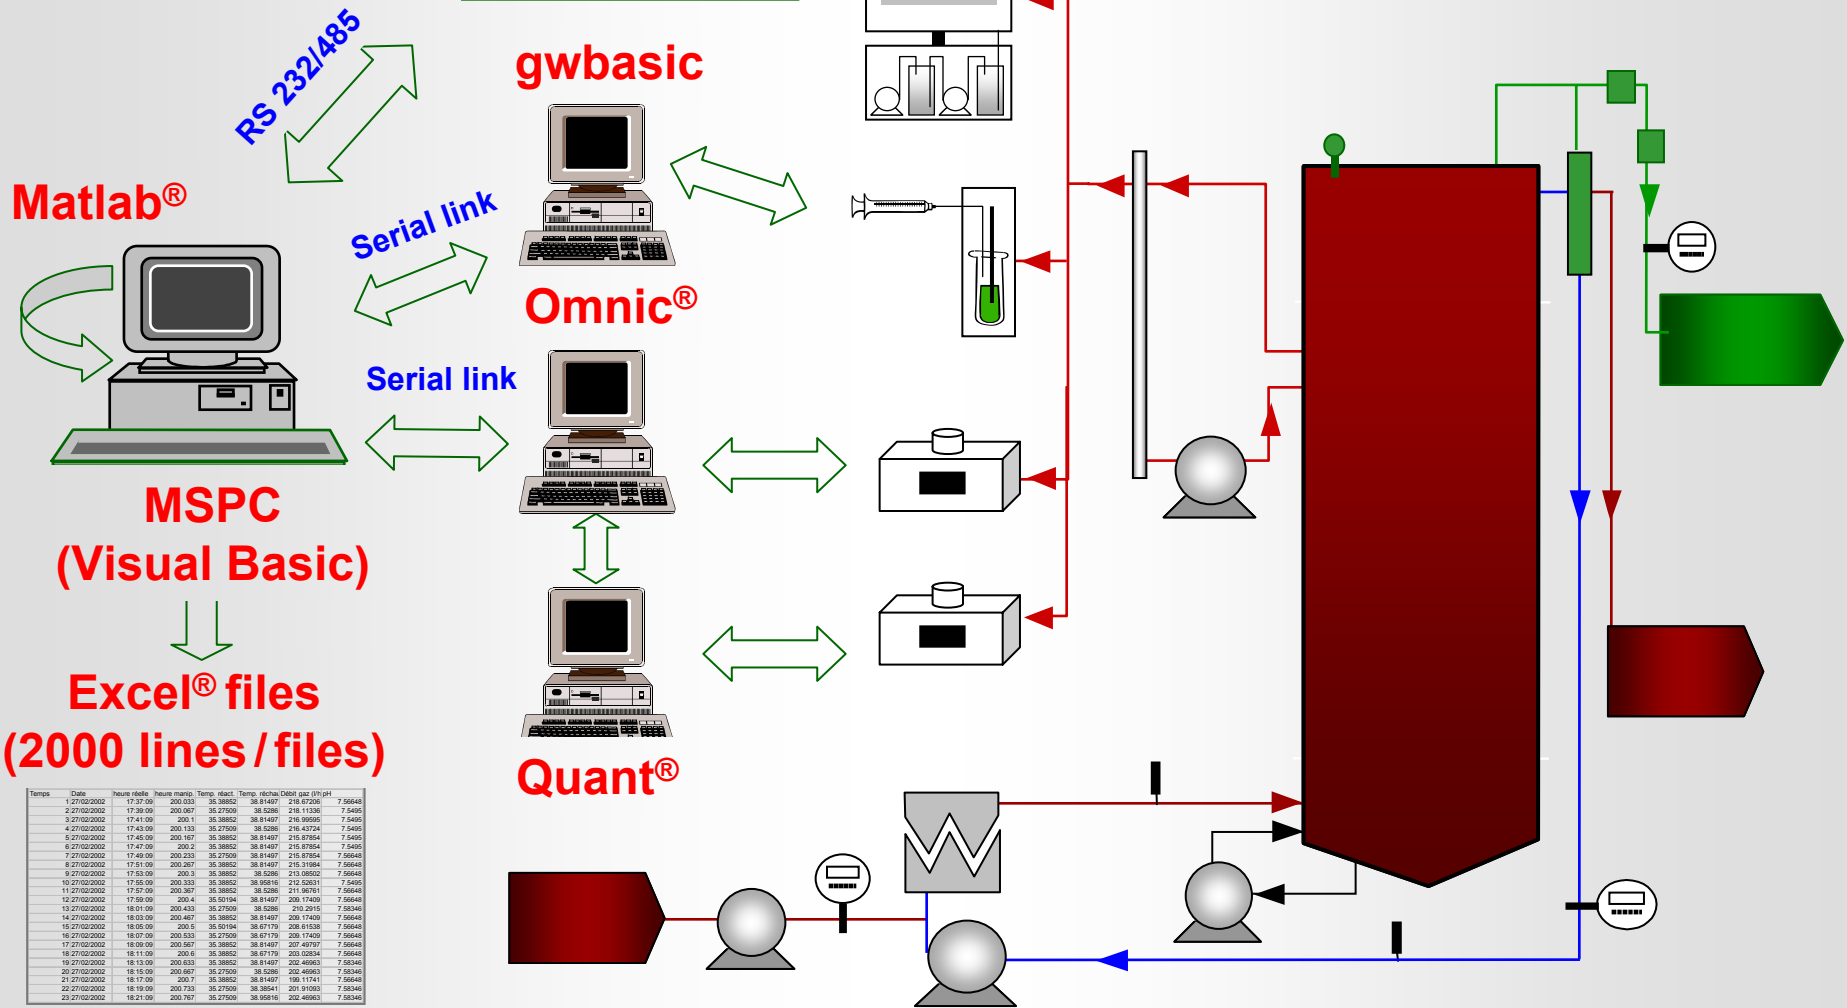

# Software Architecture

## I/O Board + PLC

To the actuators (4-20 mA, 0-10 V, ...)

From the sensors (4-20 mA, 0-10 V, ..)

Temps	Date	heure	Min	heure	manip	Temp. react.	Temp. réacteur	DO2	gaz	0/1	pH

# Software Architecture

☺ **It works**

☹ **It is quite complex**

↪ **Evolution on the long term ?**

(i.e., from "data poor, information rich" to "data rich information poor")

# From Supervision to Information System

## Evolution of requirements

**Richer information to be managed:** development of sensors and regulation loops, delocated inputs

**More actors can interact:** remote decisions, external constraints

## Evolution of technical tools

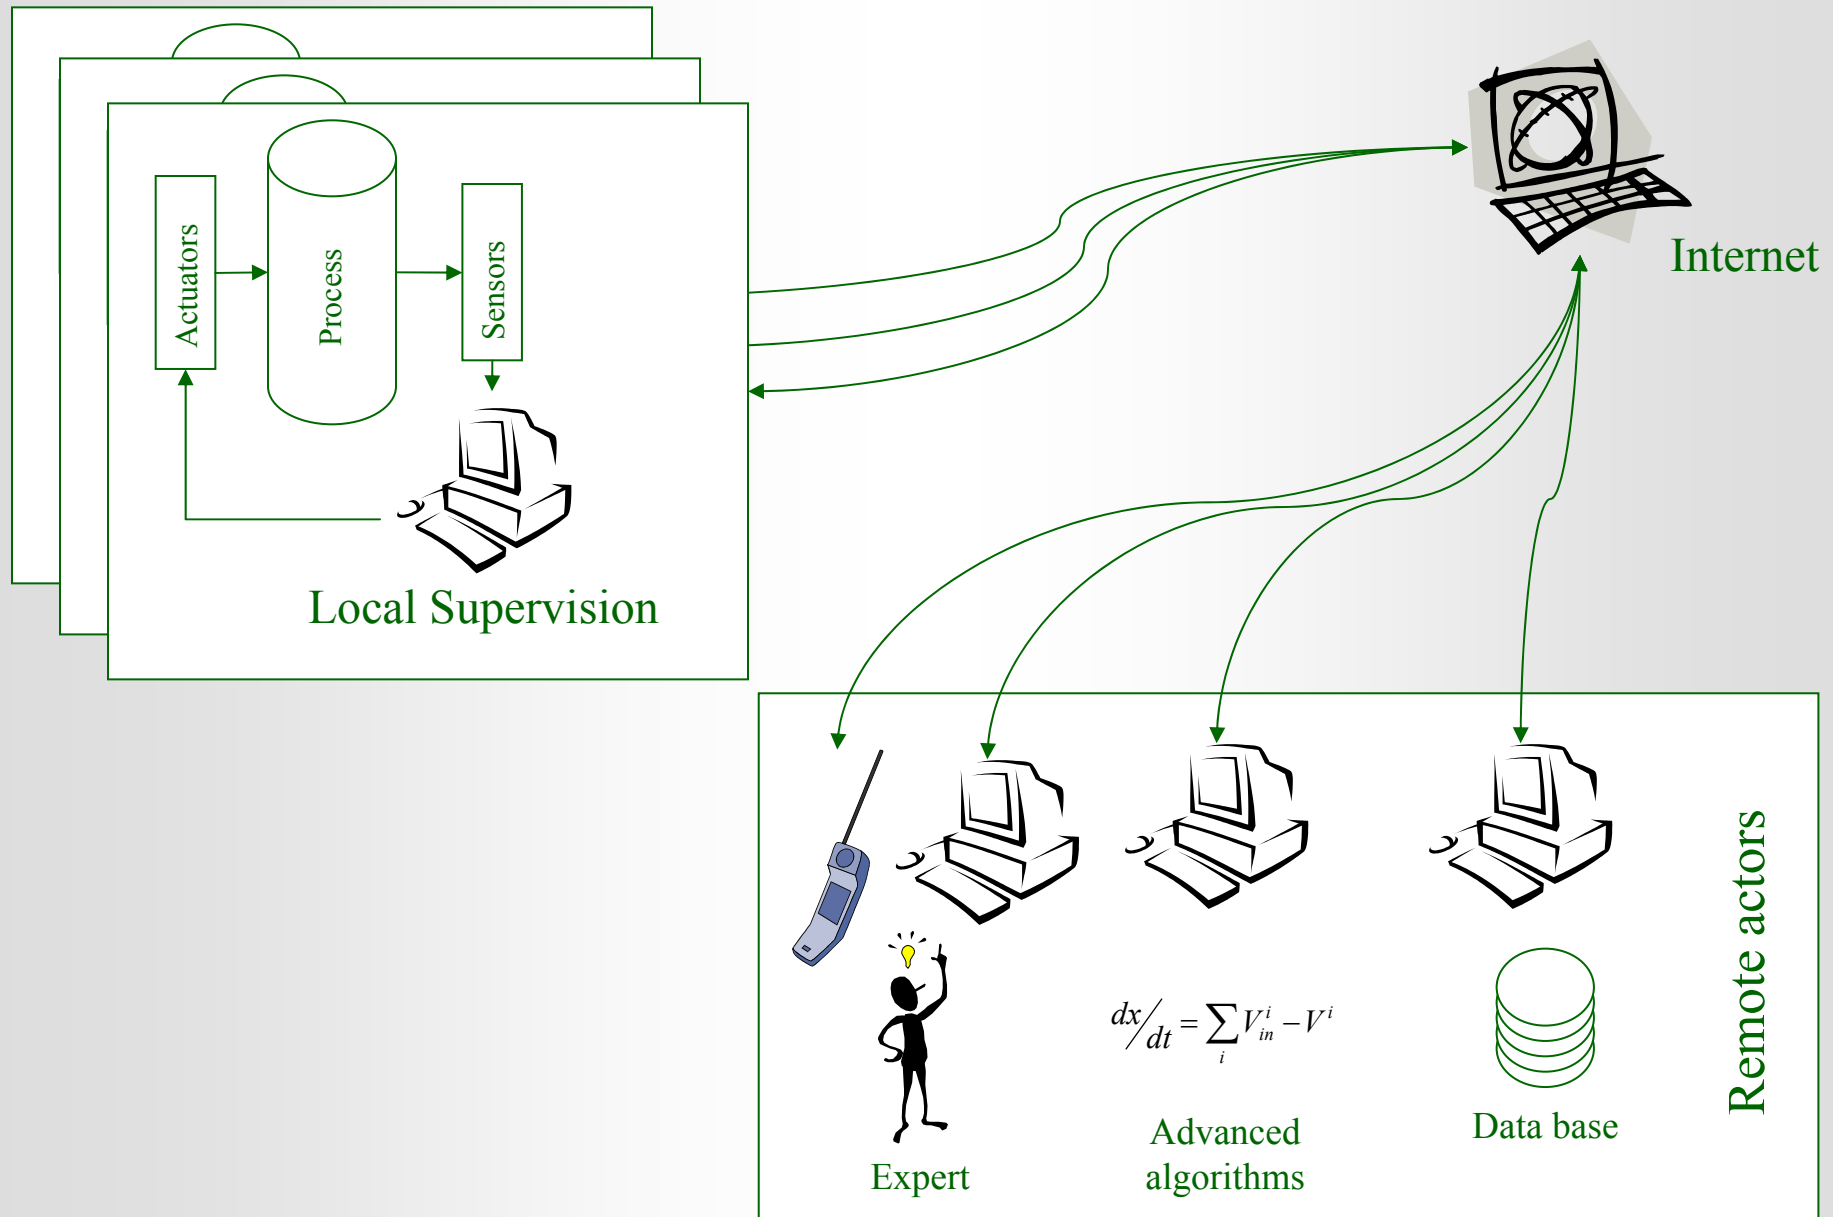

**Computer :** from client-server architecture to a virtual network of independant computers

**Connection :** availability of local network and Internet connection

# Distributed management of information

# Information System

A supervision task can be considered as an Information System

**Spatial and temporal Distribution of monitoring functions:**  
no hypothesis on the location and the treatment of each part of the supervision task.

- ✓ data acquisition,
- ✓ data display,
- ✓ data storage,
- ✓ data validation,
- ✓ process control,
- ✓ decision support system.

→ **Higher robustness and modularity** are achieved iif:

- ✓ Collected data are **structured**
- ✓ Each message is **validated**
- ✓ **Treatment** by autonomous modules
- ✓ **Storage** shared by different modules

- **Supervision and Information System**

- **Database : main ideas and implementation**

- **Integration of distributed applications**

- **Practical Realisations (the TELEMAC project)**

- ✦ **web interfaces**

- ✦ **traceability**

# Data storage

## Main constraints for storage

- Rationality :** minimal redundancy of data with a good availability of information
- Completeness :** all necessary information (to understand data) is collected and stored (traceability)
- Coherency :** to guarantee the integrity of inserted data
- Evolutivity :** to be able to adapt data storage to data evolution

## Data access

- Multi-actor :** monitoring, data-mining, web-services,...
- Standardised :** universal querying language independant of database evolution
- Secured :** control of access, confidentiality
- Performant :** keep good performances although accumulation of data

# DataBase Management System

## Functions of a Data Base Management System (DBMS)

A **Database** is a set of **structured data** so that several users can access and select data with satisfying performances.

A **DBMS** provides :

- ✓ Storage and verification functions
- ✓ Data research tools
- ✓ Administration tools
- ✓ Access control
- ✓ Communication tools

A **Database** is a logical intermediate between files and users.

A **Database** is a **server** of data, users are **clients** sending **request** to the server.

To build a DBMS, modelling of information is mandatory !!!

Fundamental and sometimes antagonist properties like **evolutivity**, **exhaustivity** and **performances** rely on the modelling of the information to store

Several types of databases corresponding to different models :

- ✓ **Hierarchic** : tree organisation of data
- ✓ **Relational** : organisation in tables and relations between tables (the most frequent model)
- ✓ **Objects** : data are hierarchised instances of objects

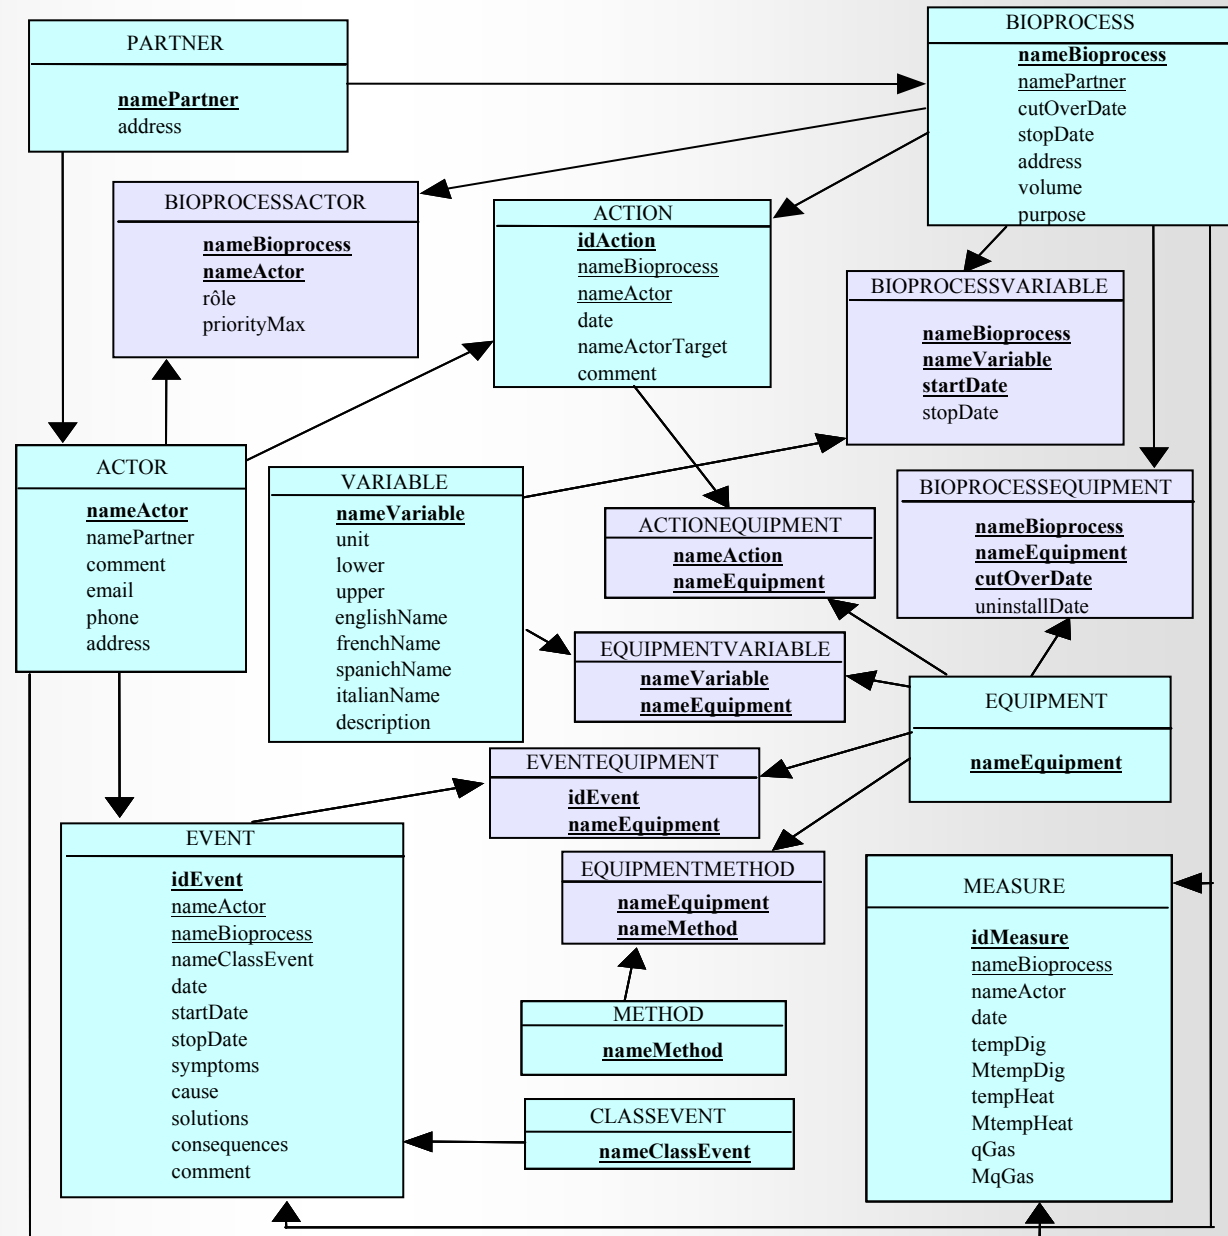

Focus on relational databases because they are efficient, widely used and have a universal request language (SQL for Standard Query language)

# Data Base Modelling

Relational model  
of the database

- **Supervision and Information System**

- **Database : main ideas and implementation**

- **Integration of distributed applications**

- **Practical Realisations (the TELEMAC project)**

- ✦ **web interfaces**

- ✦ **traceability**

# Distributed Application

## Which functions to guaranty ?

Several interconnected modules

Modularity, interoperability	heterogeneous actors, different technologic tools
Evolutivity:	evolution of descriptions should not invalidate previous software developments.
Message control:	integrity, authenticity, confidentiality
Several and simultaneous access	

Need of an *ad hoc* language to formulate and validate messages, independent from sending authors and addressed actors but open enough to support evolutions

Developpment of an XML language

# XML languages

## Definitions

**XML** : eXtensible Markup Language

Language dedicated to formalization, storage and dynamic exchange of information

Explicit Separation of content and form

Description by tree of mark-ups

**XML** : meta language to define a language  
(*i.e.*, vocabulary *and* grammar)

```
<measurement>
  <ph>6.5</ph>
  <temp>35</temp>
</measurement>
```

## Some examples

XML is a W3C Norm

↳ MathML, ChemML, XHTML, SMIL, WML ...

# Structure of an XML document

```
<?xml version="1.0" encoding="UTF-8"?>
<!DOCTYPE plantML SYSTEM "PlantML.dtd">
<plantML>
  <acquisition plantID="33.11100.200" date="2003-01-20 14:00:00">
    <sensor>
      <value label="vfaDig" unit="g/L" from="1">1.4</value>
      <value label="vfaDig" unit="mg/L" from="2">1450</value>
      <value label="pCH4" unit="%">68</value>
    </sensor>
  </acquisition>
</plantML>
```

## Header :

This is an XML file, following the model called *PlantML.dtd*

## Elements :

Textual data between a couple of markup opening `<>` and closing `</>`.  
A mark-up can be completed by some arguments

## Verification :

*Well-formed* : syntax and tree are correct

*Valid* : mark-ups are conform to the document model

# XML language modelling

## Strategy

**Compared to relational database elaboration :**

Strong analogy between entity and éléments, and between relations and hierarchy

**Treatment and flow diagram :** identification of all senders and receivers, determine minimal knowledge needed to correctly understand each message

**Simultaneous conception of the XML model and the SQL model :**

Models are validated when same information is concisely and correctly represented under the both formalisms

Data Flow Analysis

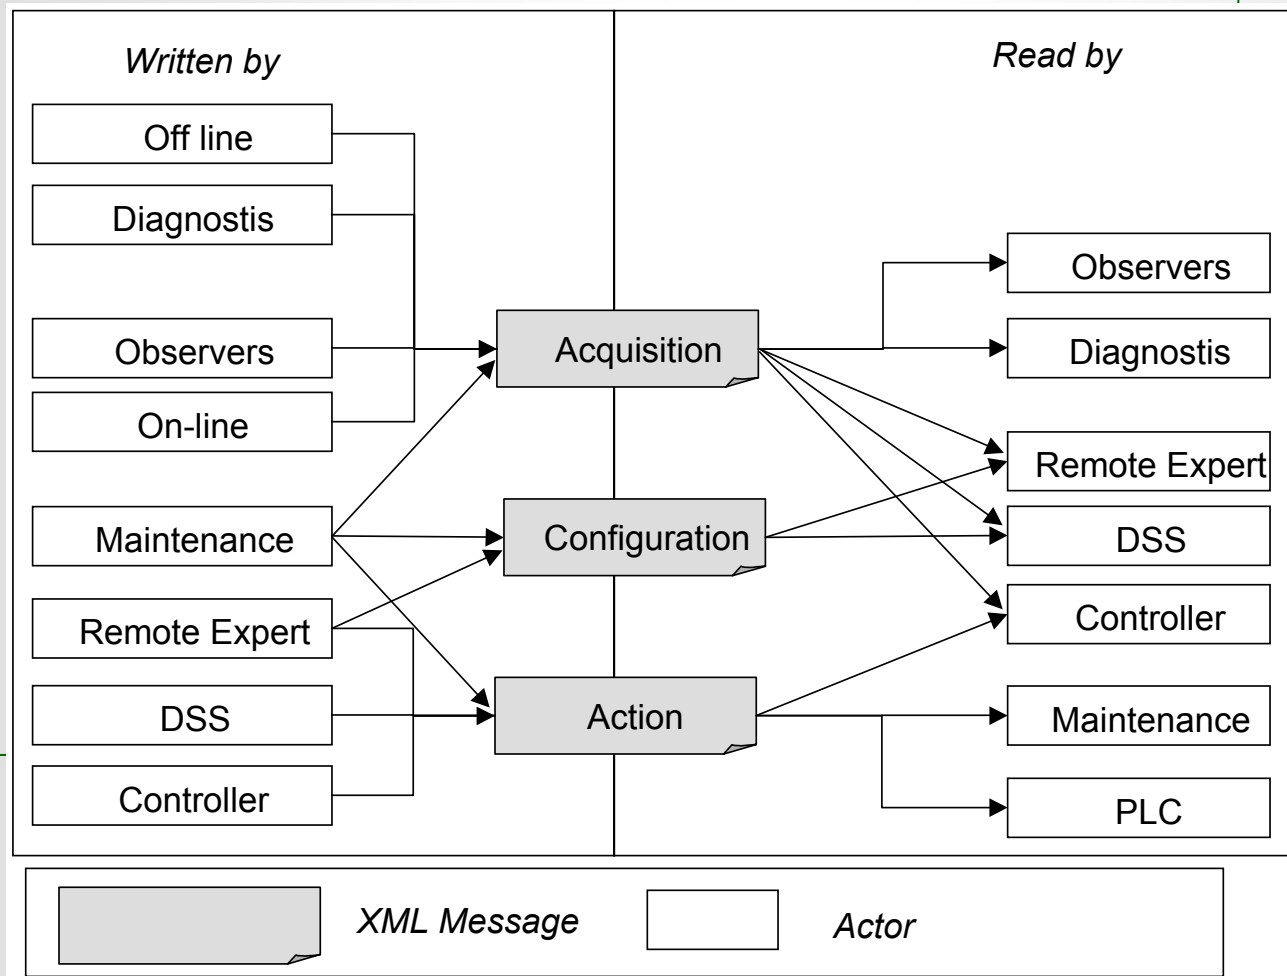

Relational Analysis

# XML language modelling

## Example of a treatment diagram for a supervision task

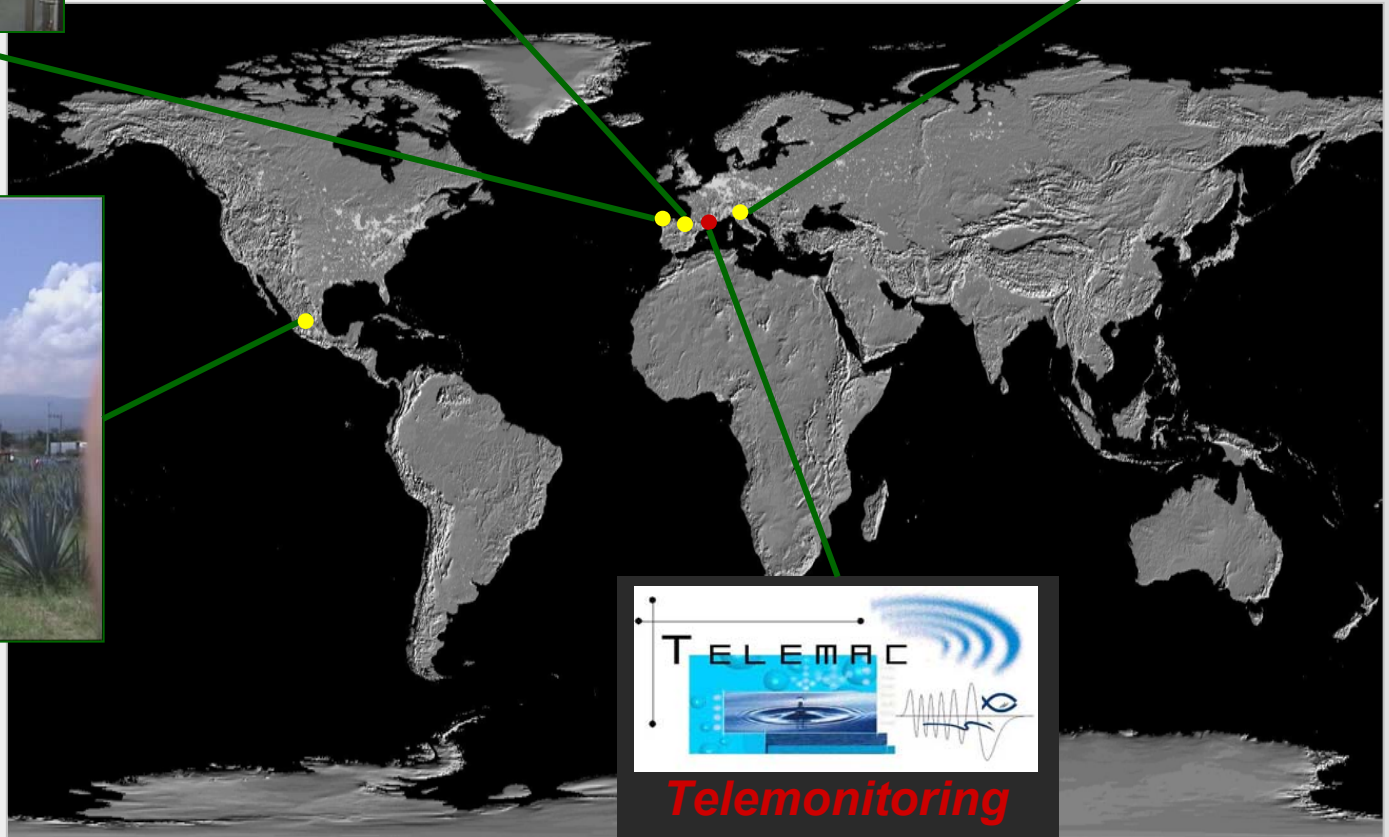

- **Supervision and Information System**
- **Database : main ideas and implementation**
- **Integration of distributed applications**
- **Practical Realisations (the TELEMAC project)**
  - ✦ **web interfaces**
  - ✦ **traceability**

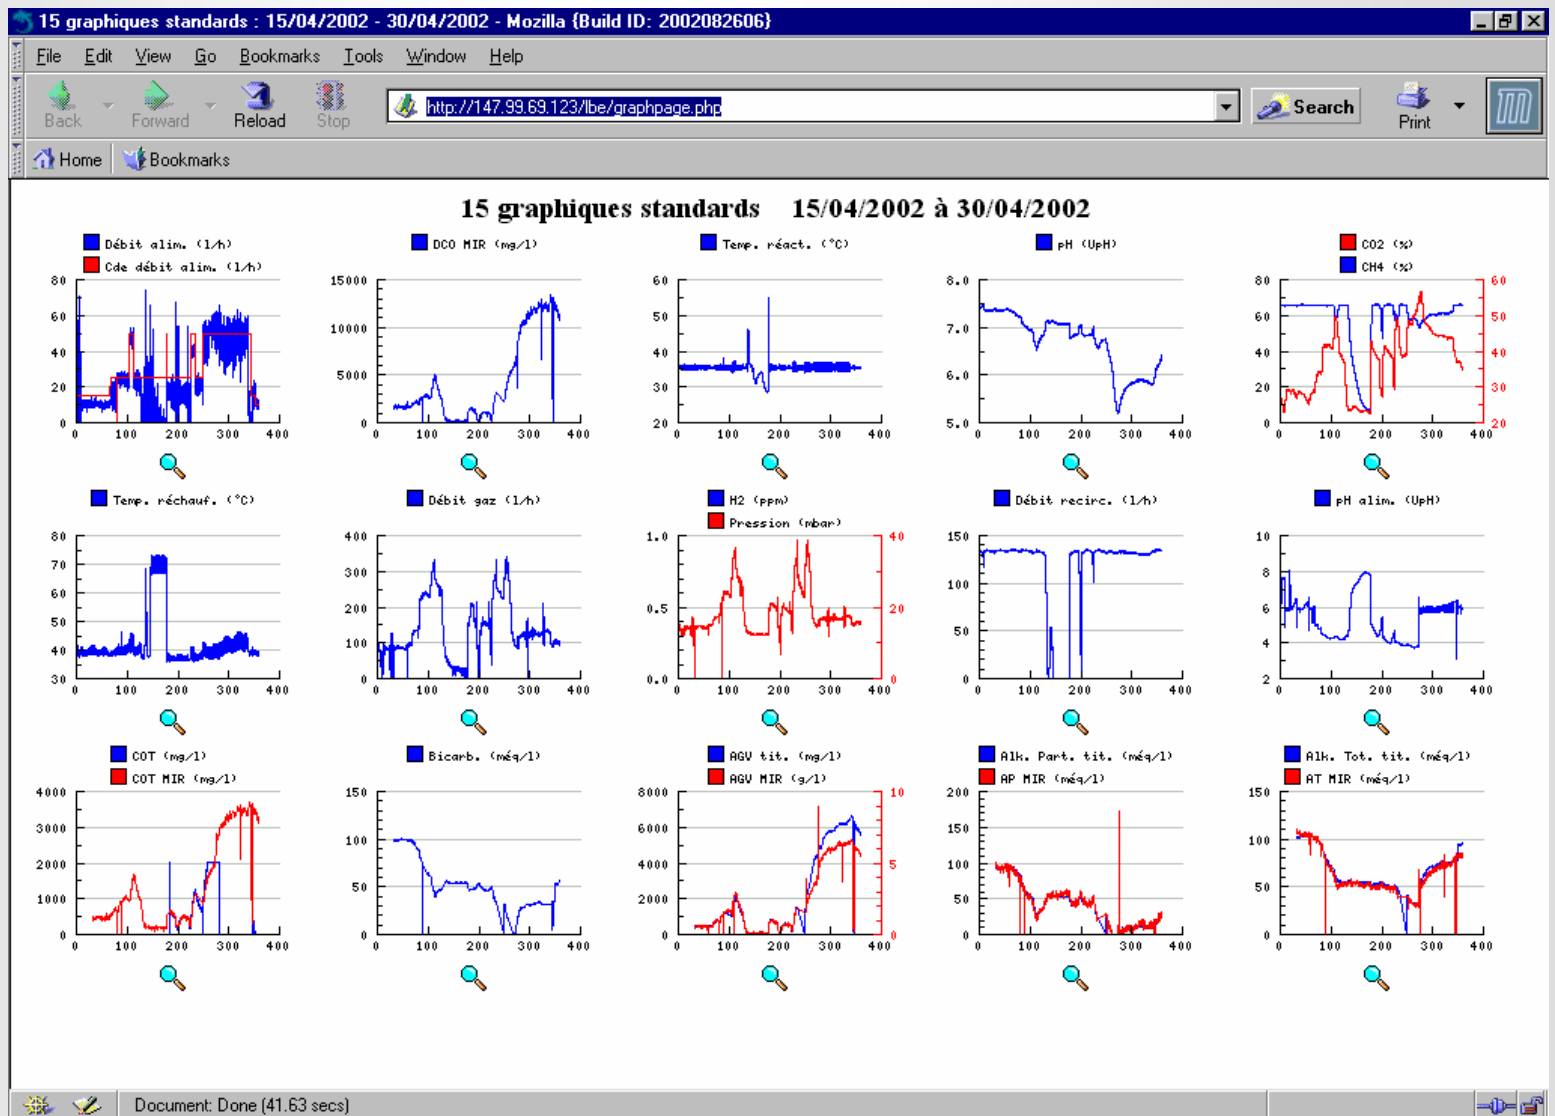

# The European Project TELEMAC

**Telemonitoring  
Control Center**

# Web access to the database

- PlantML: ✓ Multi-language graphical display and closed loop control,  
✓ Web interface for expert comments, off-line measurements, ...

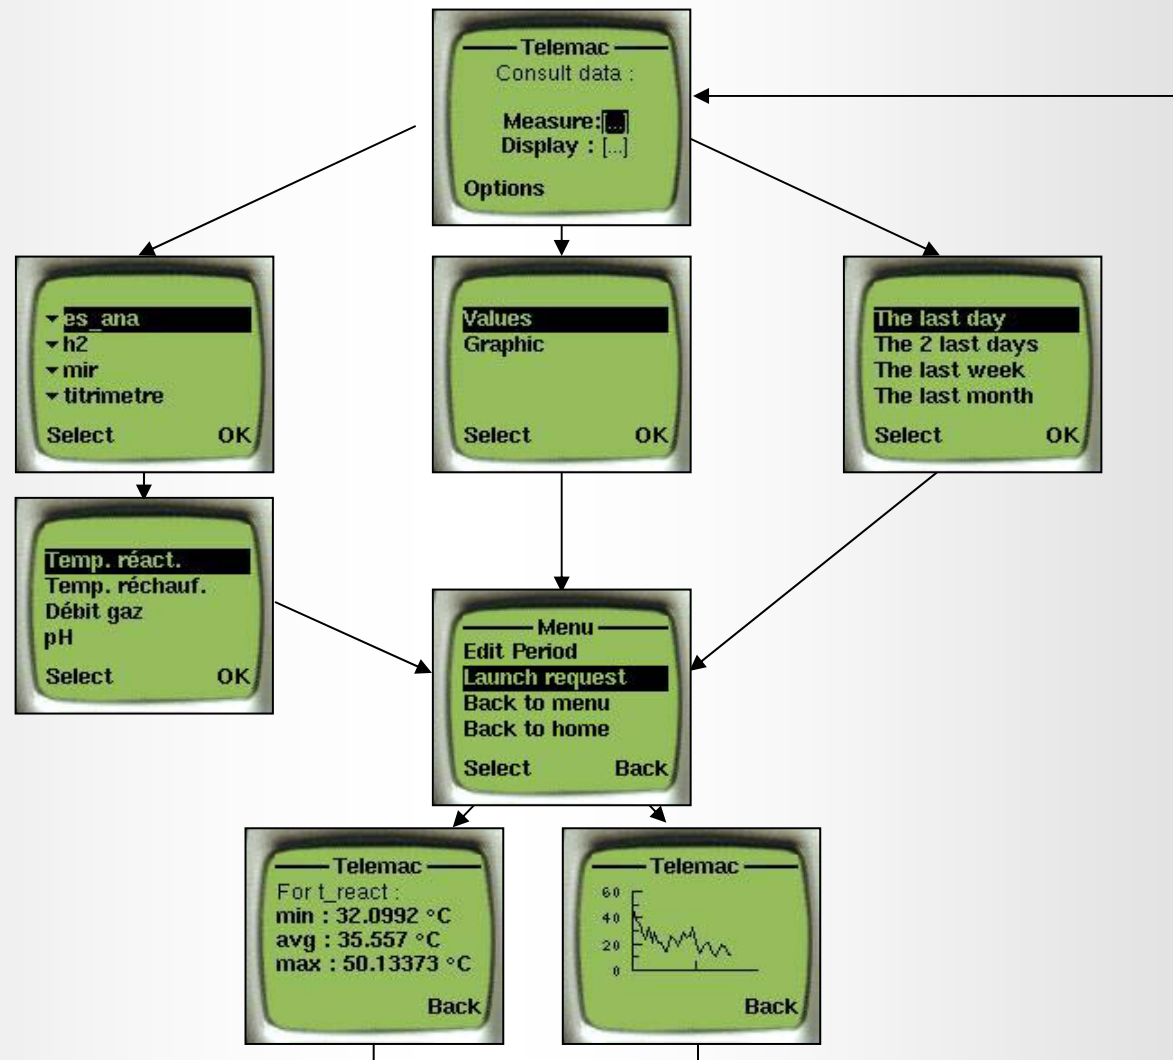

# Wap access to the database

Easy acces to the last data from a mobile phone

## Data Base (+ XML)

- ✓ **Traceability** (☺ for understanding)
  - ✓ **Data validation** (☺ for on-line control)
  - ✓ **Generalization** over several locations ( $1+1>2$ )
- ↪ Need of **information modeling** !

***Many thanks to you for your interest !***

***And I will be happy  
to answer your questions...***
